Tnks Josh;

Looks like this is going to be a long thread..... The dummy load is hooked up on ant 2 The ant 2 lite is lite along with the bypass lite.. Will not clear. Locked up.... FROZE

Guys
Tnks so much for ur help,, but the issue has been the unit is locked up on the dummy load and/or antenna and will not do anything. Was wondering if any one else has had this problem.

According to the canadian hf band plan 24.9 is the top of the band edge for the 12 m band.

one possibility is to phone the tech support folks at LDG and ask the specific question about band edge operation, ask LDG if the tuner goes to the band edge and tunes no further due to the bandwidth allocation for assigned mode.
eg ssb 6 khz max bandwith for example ,sstv has a different requirement for example than ssb operation .

Refer to the table for each itu region eg region 1 vs 2 vs 3 there not all identical and the regulations for your country may have have some specific modifications to meet the itu intent.

I suspect the reason you have got a no fault found analysis is there is likely operator error on your part.

My previous tuner eg Kenwood AT-50 kept you in band on all band and if the radio had no tuner attached it would transmiter outside of assigned hf band plans which was not a legal ham operaation.

Have you possibly overlooked the bandwith associated with your signal(and mode of communication eg ssb, sstv, other digital mode cw etc) and the tuner is legitimately cutting you off to keep you within 12 m band allocation meaning you have to operated below the band edge extreme.

Subject: [LDG-auto-tuners] LDG 600 pro one month old problem

Hello Al, purchased an LDG 600 pro auto tuner less than 30 days ago and had the following problem. My conditions were as follows.
Using the ts 590 connected directly to the tuner with 100 watts and into a 50 ohm dummy load, before connecting to an antenna.
The pwr switch turned on propery and the ant 2 confirmed tuner setup.
I started checking all bands from 1.8 thru 21mhz and the ant tuned properly with the threshold at 2.0.swr.
When I got to 24.9, the bypass lite turned on and and the tuner would no longer respond and locked up.

Removed the dc pwr and reconnected and the bypass lite would not turn of. Pushing the pwr switch of and on I could not hear the relay click on and off and the bypass lite would not go off. Momentarly pushing the tune button would not turn the bypass lite of either.
The unit was sent in for repair to LDG and the tech reported no faults with the unit.

Thank you LDG for the fast turn around, received the unit yesterday and went thru the same testing and when I got to 24.9 it locked up agn just like before. Any help would be appreciated with regard to my problem with this tuner.

Just some general comment you may have overlooked

Which brand is the TS590 is it a Kenwood?. My internet search makes me think this is possibly so.

Its totally unclear from your question as to what your dealing with for both a rig and antenna you know these facts but other responders including myself are tying to second guess what your doing

Have you read your printed LDG operating manual shipped with the tuner or downloaded the pdf online version from LDG web site. Have you also checked the faq section for this specific tuner

My kenwood TS50 automatically reduces power to the output during tuning to10 watt level when using the tune button on the rig as others have stated are you reducing power? see my comment re correct mode during tuning see your rig operating manual.

Are you reducing the power output during tuning and also using the right mode eg cw instead of ssb operation, tuners generally need a low level continous signal to use during tuning operation.

The resistive dummy load is a 1:1 match as its a 50 ohm load against the theoretical value for a solid state rig wanting a output impedance of 50 ohms.

A reactive component due to real world conditions of inductance or capactive reactance is present in all real world antennas and the tuner will not react to situations thats close to a theoretical perfect match either tuning and will generally go into bypass mode of operation if the antenna presents value close to theroretical to its analysis circuitry.

Are you possibly a new novice operator? or possibly a older ham used to the days of tube operation who has possibly overlooked the antenna theory that's been the same for 50 or 60 years.

You must remember these basic principles taught in basic antenna theory class

The tuner is only making the rig happy and is not making the physical antenna corrections, remember your swr profile for your antenna being a dish shape as you move away from the resonant point

Also remember your swr is a ratio formula and two impedance will give you a same numerical value for example 100 ohms and 25 ohms both give you a 2:1 ratio

Most new solid state rigs begin powering down the output above a ratio of 2.5:1 to save the final transistors.

If tuner sees an acceptable antenna match it may not react once the intial tune is finished also remember it will operate back to its memory data setting the next time it see the same antenna connected.

this will make you think the tuner is not operating properly ask LDG tech support if they cleared your memory during the service checkout , they will likely use a test combination of components to give a range of antenna configurations to test the operation of the tuner that the nominal ham would not have on the test bench.

Question why would you connect a 50 ohm dummy load to the antenna #2 position, is your rig so old you need to manual tune up as in days with a tube rig ?.

The technical specs give a range of impedances its designed to tune into to see if your not making an operator error. HAVE YOU TECHNICALLY ANALYZED YOUR ANTENNA WITH AN ANALYZER

my KT series tuner goes into bypass right away when presenting a 40 m loop(measured at 100 ohms or a 40 m mobile vertical tuned mid band used in a stationary application that been tested with a computer minivna analyzer that shows 50 ohms resistive and a capacitance reactance value which the tuner is satisfied with

Once most electronic tuners see 1.5:1 they generally may fine tune to a lower final value but not necessarily 1:1match.

The newer tuners with chip control do have a factory set of parameters they work to but the manufacturers don't necessarily publish that information. they have capacitors and inductor present to allow matching most nominal antenna load configurations

Here is a copy of Dwaynes response from another email reply for a different tuner model regarding minimum threshold operation for a different model

Dwaynes reply to another user was as follows

This is incorrect. The setting for the threshold is only for the starting threshold when in Auto mode. It has nothing to do with the final SWR.

The tuner always looks for the best match when it does a full tune, no matter what the starting threshold is set to.

All newer models have the minimum threshold range selectable between 1.7 and 3.0.

Dwayne Kincaid
LDG

> The lower you set it [the starting threshold] the lower SWR it will match to but takes longer.

Have you tried emailing Dwayne Kinkaid from LDG on this forum

I suspect his reply may be similar to mine but less general since he has access to the design criteria they use in there tuner design

He likely will quizz you about some of the basics im asking about what your doing?

5539. LDG AT-600Pro Autotuner lock up info.

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2012-07-15 20:01:46 UTC
From: mcyman
Topic: 5539 Message: 5539

Hello LDG owners,
I have been reading with interest posts with regard to the Lock up Problems with the LDG AT-600Pro Auto tuner.

When I was looking for an Auto tuner I read EHam REVIEWS , and noticed that the 600 Pro tuner had one of the lowest LDG scores, which was a 4.2, and read that customer support was an issue for some owners.

Knowing that I still purchased the 600 pro hoping, like some other owners that I would not experience any issues!
As others had mentioned the OWNERS Manual leaves a lot to be desired, and took me awhile to find out that the Bypass or when the tuner is powered off the Transceiver(TX) port is connected to ANT2 Not ANT 1! Nothing is mentioned in the owner's manual !

I see that one of the Owners of the LDG 600 Pro is having issues with his tuner locking up , and after sending it in for repair, it came back with the same lock up issues !

What is interesting is I have not read any issues about the AT600 Locking up in this Group or on EHAM?

However I have personally experienced a Lock up problem with my LDG600 Pro tuner during normal operations, to the extent that it would not, turn off, and none of the push buttons would function!
The only way that I could clear the fault was to unplug the DC Power wait a few seconds and plug the DC power back in to the LDG tuner!
This particular issue has happened at least 3 times.
After the Lock up is cleared, the tuner seems to operate normally again!
By the way I looked for a Serial number on my tuner, but none exist? However there is a number 410-586-2177 printed below the LDG address, also says made in Taiwan.
Any thoughts would be appreciated.
Rob N8RT

5540. Re: [LDG-auto-tuners] LDG AT-600Pro Autotuner lock up info.

Yahoo group: LDG-auto-tuners (2010 — 2017)

A multitude of thoughts come to mind when I hear interference stories and unexplained random rf related events or dc power supply related incidences .

very specific details are generally needed to respond properly to technical issues to allow careful comment and that's why responders give such varying opinions to a simple question trying to second guess the possible installation problem or antenna related issues that interact with the equipment or equipment power faults.

One can ask many detailed questions in response to your query

Due to the fact there can be a whole gamut of dc power supplies used not just one specific vendor involved .

In the ham hobby not all circuit designs are pure dc outputs especially if switch mode designs are used.

Have you tried a simple old car battery as a dc source with no power supply attached and isolated this down to radio operations to confirm rf is or isnot not getting into the control leads of the tuner and impacting operations between the radio and the tuner

Does the problem occur on just one hf band or is it at random on any band you work, you have not spelled out your specifics in relation to your 3 incident situation
.
For example what brand of dc power source are you using? Is the power supply design rf clean after examining using an oscilliscope to observe whats on the power leads both positve and negative leads.

For example some power supply reviews given in QST point out the wide variances in output dc purity in comparison to a dc battery.

Maybe the dc fix is as simple as some small rf bypass capacitors are need to filter the rf to ground on both output leads and keep it away from the sensative electronics in the tuner circuitry.

I have looked at the dc leads on a modern solid state rig tied just to just a 12v battery with no power supply attached and found lots of low level rf on the dc leads (found using an oscilliscope this is not using a plain electronic digital meter) as input impedance of instrumentation varies all over the map and can maks what is really going on on the leads.

most current owners manual of modern electronically sensative gear make mention of proper rf grounding paths from both the rig and tuner to a seperate shack ground bus that is not related to the dc power leads.

How close to the rf output coax are you for example with the tuner control leads as the power level at 100 w and can induce small rf signal levels into sensative adjacent electronic wiring for the tuner control eg a 3 pair #20 gauge wiring betwen the rig and tuner jacks for example.

It is hard for the manufacturers to design for all ham configurations or try and second guess how each operator has configured there shack (see arrl handbook for example)or what specifc dc power supply is used to power the dc input. my ldg tuner for example sources it from the hf rig due to the tune button operation

How much power are you using somtimes systems are clean at 100w level but fall apart at 500 or 1000 w levels due to simple induction into system wiring

The lockup sound like possible rf related as it so erratic and hard to chase down makes me thing of purity of dc power and rf influence on the power leads possibly at the same time.

some problems can be only appear in one band and leave other bands clear of problems, you have not noted the specifics of when your problems have occured, what is your soil moisture content for example it impacts your rf ground preformance, is time of year involved an how good the rf path is length etc
.
Reemmber a car gives you a solid rf return path due to metal body being used for the return path in comparison to the home stationary environment induction into the ac wiring etc impacting the dc power supply preformance for home use in comparison to the dc wiring in the car and the single source dc alternator.

For example at my location I can go from dry soil and high ground resistance to soaking wet in the spring time and very low resistance impacting tuner and rig preformance .

I have also been in a consistent enviroment on the west coast of Canada that might be generally moist all year round.For example I have a rf external driven ground rod network that consist of 5 ground rods to compensate for the variable conditions .

Your description of the issue make me think of more than one cause is likely involved.

Troubleshooting is never easy and take lots of work to resolve sometime with equipment one does not have.

Have you contacted Dwayne Kincaid from LDG on this forum and given him very specific details eg lead length seperation spacing between wiring etc and exactly how the rf ground path is configured type of dc power source used etc bands used when problem ocurs small details only you know.

Have you used coax braid or just plain coated wire for the ground path wiring method, small things can make a huge preformance difference

Ive seen coments about rf filtering the tuner leads from Dwayne before for other model manufacturer by them

One has to ensure that all shack wiring principles are followed to avoid problems not everyone is careful or understand the seceptablility of rf factors.

Everyone rf path has different characteristics depending whats used, and how long wire leads are etc

Many factors can make your installation work ok and somebody else has nothing but trouble for example is the rf ground for all your equipment ground terminals tied to in the shack to a common point or daisy chain from qeuipment to equipment instead of individul leads to the single rf ground bus point.

I have seen this control wiring path between equipment get messy and complicated in a telco environment with rf transmitters electronic switching etc

Hello LDG owners,
I have been reading with interest posts with regard to the Lock up Problems with the LDG AT-600Pro Auto tuner.

When I was looking for an Auto tuner I read EHam REVIEWS , and noticed that the 600 Pro tuner had one of the lowest LDG scores, which was a 4.2, and read that customer support was an issue for some owners.

Knowing that I still purchased the 600 pro hoping, like some other owners that I would not experience any issues!
As others had mentioned the OWNERS Manual leaves a lot to be desired, and took me awhile to find out that the Bypass or when the tuner is powered off the Transceiver(TX) port is connected to ANT2 Not ANT 1! Nothing is mentioned in the owner's manual !

I see that one of the Owners of the LDG 600 Pro is having issues with his tuner locking up , and after sending it in for repair, it came back with the same lock up issues !

What is interesting is I have not read any issues about the AT600 Locking up in this Group or on EHAM?

However I have personally experienced a Lock up problem with my LDG600 Pro tuner during normal operations, to the extent that it would not, turn off, and none of the push buttons would function!
The only way that I could clear the fault was to unplug the DC Power wait a few seconds and plug the DC power back in to the LDG tuner!
This particular issue has happened at least 3 times.
After the Lock up is cleared, the tuner seems to operate normally again!
By the way I looked for a Serial number on my tuner, but none exist? However there is a number 410-586-2177 printed below the LDG address, also says made in Taiwan.
Any thoughts would be appreciated.

Topic: 5541 Message: 5542

Hi Richard,

If its like the YT-450, I doubt you can, but if the purpose of clearing the memory is because you are using it with a different antenna, it will take no longer to do a full tune from a wiped memory than from a previously set frequency. After a few sessions on another antenna, it will just override any operating parameters that might be stored on a previously used/adjusted antenna.

Just keep using it would be my advice.

5544. RT-11 to IC-706 cable pin connections

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2012-07-21 19:18:52 UTC
From: yg@internetsmallfry.com
Topic: 5544 Message: 5544

Does anyone have the correct pin connections for the cable that goes from the DB-9 connector on the RT-11 to the 4-pin tuner connector on the back of the IC-706?

There is a file in the Files section of this group called "RT11 Remote.GIF" that shows a connection diagram but I can't see how it can be correct. It shows the 706 pin 2 ("Start") as going to pin 2 on the RT-11... but pin 2 of the RT-11 is the "Tuner bypass" pin whereas pin 3 of the RT-11 is "Tune control". Seems like pin 2 on the IC-706 should go to pin 3 on the RT-11, not pin 2.

Since that connection appears to be wrong, I don't have a lot of confidence in the connection shown for pin 1 on the IC-706 (the "Key" pin) going to pin 7 on the RT-11 (which the RT-11 manual describes, rather uninformatively, as "Radio out. This line is used in the tuner interface with Icom and Alinco radios.").

My best guess, from searching all over the web, is:

ICOM RT-11
1 <-- 7 (NOTE: NOT sure about this one)
2 --> 3
3 --> 1
4 --> 8 & 9

RT-11 pins 2, 4, 5, and 6 are not connected.

Is that correct?

Thanks...

I have a new YT-100 and just love it. Today I bought a serial to USB cable from radio shack and connected it with my CAT cable. When I tried to connect to HRD it would not read the frequency. I tried quite a few steps, as recommened by HRD but nothing worked. Any help would be appreciated.

Check your port speed I think the YT-100 needs 4800 so the radio and HRD need to be set to 4800.

I think we found the problem.My computer is a new Dell laptop with 4 USB ports. Two are USB3.0, and two are USB2.0. I have a wireless mouse and an ipad and neither device works in the USB3.0 port. I had the cable from the radio plugged into one of the 3.0 ports and I am betting that if I plug into a 2.0 port it will do just fine(I hope). I ordered a cable from RT Systems and will let the group know if that works. I got the first cable from Radio Shack and it had the prolific chip set. In reading some of the posts it seems people are having problems with that chip set. Thanks for your reply.

You might want to check out USB 3.0 backward compatibility. USB 2.0 devices are suppose to work on USB 3.0.

Rick,

You may be correct. I can't figure out how that would work. You should go by the diagram on the LDG web site. Click Products, Discontinued Misc, Discontinued Cables, then "RT-11 to Icom" wiring diagram.

Ahah! THERE it is! I searched high and low looking for that diagram and couldn't find it; obviously I looked everywhere except in the right place. :-)

The way that diagram shows is the way I wired it up (meaning that it appears I guessed correctly), and it does not work. The IC706's front panel Tune control puts it into Tune for less than a half second and then stops tuning, with the SWR still very high. It does this on any band, and with three different antennas and two different IC-706MKIIG's. Both IC-706MKIIG's tune correctly with a Z-100, an IT-100, and an AT-7000. And, the RT-11 works correctly with its RT-11 Remote box.

I haven't used the RT-11 for a few years but I do recall several years ago that I tried to use it with the 706 in my truck and never did get the 706's front panel Tune control to work correctly. I set it up in the truck with the RT Remove box and then got distracted doing other things, so I never did get around to finding out why it wouldn't work correctly with the 706's Tune control.

I guess I'd still like to get the RT-11 to work with the 706 if I can, since I'm now setting up an emcomm station in my motorhome and wanted to use the RT-11 for that since all my other LDG tuners are otherwise assigned. The firmware (I assume that chip with the paper label is the firmware) is rev RT1.3. Is there a later firmware chip available that I can try?

I think we found the problem.My computer is a new Dell laptop with 4 USB ports. Two are USB3.0, and two are USB2.0. I have a wireless mouse and an ipad and neither device works in the USB3.0 port. I had the cable from the radio plugged into one of the 3.0 ports and I am betting that if I plug into a 2.0 port it will do just fine(I hope). I ordered a cable from

RT Systems and will let the group know if that works. I got the first cable from Radio Shack and it had the prolific chip set. In reading some of the posts it seems people are having problems with that chip set. Thanks for your reply.

Right, that’s what backwards compatible means. 3.0 will support older versions (2&3). 3.0 will not work with 2 or 1.

Yes, but 3.0 will not work with 2.0 if I read the post right. So if you have something new that must have 3.0, you can’t use 2.0. Did I say that right? Time for a pill!!

So now it is 3.0. D***!!! It is always something new you have to buy. I never could tell much difference from USB 1.0 to 2.0 except the price. How about we quit buying their non-backward compatible s***. At least 1 and 2 would work together. My wallet looks like a elephant stepped on it from the bad economy now.

Rick,

You may be correct. I can't figure out how that would work. You should go by the diagram on the LDG web site. Click Products, Discontinued Misc, Discontinued Cables, then "RT-11 to Icom" wiring diagram.

Rick,

Wiring it correctly could have damaged the tuner. Processors were not very forgiving 15 years ago as they are now.

If it does not work when you make the correct cable, it will probably need to be sent back for a checkout.

We do not have any upgrades for that model.

>
> The way that diagram shows is the way I wired it up (meaning that it appears I guessed correctly), and it does not work. The IC706's front panel Tune control puts it into Tune for less than a half second and then stops tuning, with the SWR still very high. It does this on any band, and with three different antennas and two different IC-706MKIIG's. Both IC-706MKIIG's tune correctly with a Z-100, an IT-100, and an AT-7000. And, the RT-11 works correctly with its RT-11 Remote box.
>
> I haven't used the RT-11 for a few years but I do recall several years ago that I tried to use it with the 706 in my truck and never did get the 706's front panel Tune control to work correctly. I set it up in the truck with the RT Remove box and then got distracted doing other things, so I never did get around to finding out why it wouldn't work correctly with the 706's Tune control.
>
> I guess I'd still like to get the RT-11 to work with the 706 if I can, since I'm now setting up an emcomm station in my motorhome and wanted to use the RT-11 for that since all my other LDG tuners are otherwise assigned. The firmware (I assume that chip with the paper label is the firmware) is rev RT1.3. Is there a later firmware chip available that I can try?

Hi Robert,

I'd be the wrong guy to ask about HRD as I've never used it. There should be several knowledgeable users on this group that have interfaced the radio/LDG tuner/HRD with success.

Good afternoon, Dwayne.

You mean wiring it INcorrectly could have damaged the tuner, right? I never did wire it incorrectly... as I said I guessed right when I first wired it up, and it was wired as shown on the diagram on your website.

> If it does not work when you make the correct cable,
> it will probably need to be sent back for a checkout.

I can do that, but like I said, the RT-11 works correctly with the RT-11 Remote box, so does that indicate anything? At the very least it should indicate that there is no damage in the RT-11 itself.

Despite all of that, if it turns out there is something broken, will you have the parts to fix it? And what are the chances it'll cost more to fix than the thing is worth? As I said it does work correctly with the RT-11 Remote, but using the RT-11 Remote is not practical in the emcomm setup in my motorhome.

Hal,

"Easy" is a relative term. What is easy for some may be very hard for others. You will need to know how to solder small parts.

The replacement bulb is available from www.cheapham.com.

If you get the bulb and it's beyond your capability, LDG will always install it for you at no charge.

Phil,

Try a 40M Hamstick with the IT-100, you'll get 20 - 80. Don't expect miracles on 80. Then plug that 102 whip for the high bands.

Robert,

If you're using Windows 7, there are known issues with USB/serial adapters and HRD. Try recycling an old PC with a real serial port.

Hello Terry.

I have just found out on my 200Pro and IC-7000 that to power up I need to also have the Astron power supply powered off first.

Then I have to turn the power supply on along with the Radio while holding buttons in on the 200Pro.

So just remember to have all shut off first, including the power supply. I had problems till I shut the power supply off.

I hope that helps.

Search ebay for:
80, 40, and 20m, ham sticks AND quick disconnects for all the antennas. The 102 probably OK for 15-10m. 6m is 1/2 wave, so that not so nice to the tuner. Nor is 20m, as this is 1/8th wave.

The very best set up is a screwdriver antennas and no antenna tuner at all (sorry)...

Hello Tim,

We never made a remote for the AT-11 tuner, but we did make a remote for the AT-11MP tuner called AT-11MP-Remote and it was different than the RT-Remote for the RT-11 tuner.

Also at one time, we made an adapter board to allow the AT-11 tuner to use the AT-11MP-Remote called the ACC-11. That interface was also different than the RT-Remote.

Since there is a rep of LDG here...

Can you tell me why my IT-100 does not seem to be out of circuit when the tuner is not turned on by the IC-7000. Sometimes, I go to a different band and the receiver seems hearing impaired. If I turn the tuner on and let it retune, it is fine, and stays that way when I turn the tuner off on the radio.

Thanks, Dwayne.

i have a Z100 that I would like to remote at the bse of my S9V43 antenna. I found this 8 year old message thread and it seems to be telling me what I need to do. I'm wondering if you remember how your effort turned out?

i'm also wonering how heavy the remote wires will need to be. The antenna is about 50 feet from my radio. Which is why I'm putting te tunner at the base of the antenna.

Thanks.

Gary,

Since no Icom tuners have latching relays, almost all Icom radios send a bypass command to the tuner when you turn them on.

Similarly, some of the Icom radios (including the IC-7000) sends a bypass command to the tuner when you use the band up/down button to change bands.

Sounds reasonable.

> Similarly, some of the Icom radios (including the IC-7000) sends a bypass command
> to the tuner when you use the band up/down button to change bands.

Also sounds right.

This doesn't answer why the tuner sometimes seems to be left in the circuit when the radio says it is not. It sucks the signals out because it has not been tuned on the band I changed to. Even though it says it is "off", I have to tell it to tune just to get the signals back on the receiver. THEN, when I turn the tuner back off, it is fine. It acts like the tuner is still electrically inline but tuned to the wrong band until I tell it to tune.

Example: Use the radio on 75M with the tuner inline, tuned to 3.950. Go up to six meters and change antennas. Receiver is deaf. Tuner indicator on the radio is not lit. Hit the tuner button, let it tune, receiver comes alive. Turn the tuner off with the radio button, it is still good. As I type this, I realize I have not run a test to see what the radios indication is for SWR when this happens. If the tuner is still on 75M and still in the circuit even though the radio says it isn't, then it should be high.

The instructions didn't say anything about making any menu changes when installing the tuner. The radio is new, and I didn't change anything on the tuner menu. Is there something that needs to be done there?

I also question the memory function. It almost always (almost always, not always) does the long tune procedure when you hit it, even though it is on the same frequency it was on the last time it was turned on. Example: Tune it on 50.125, take it out of circuit with radio button, go to another band (10, 20, etc.) awhile, come back, hit the tuner and it goes into long procedure again. I've even turned it off (radio button), then turned it right back on again, and it long tunes again.

I never use the button on the tuner.

It has never failed to tune properly.

If we need to take this off-list, please feel free to email me at ag0n at ag0n dot net.

Thanks for your advice.

5585. AT-600 Pro

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2012-08-08 16:18:14 UTC
From: shibukiau
Topic: 5585 Message: 5585

I've been using an AT-600 PRO tuner at my remote HF station since the introduction of the tuner and it has worked well until recently.

Recently the tuner started to jump off it's tune point when using the TX. The tuner holds it's tune point at the start of the QSO but then starts to jump around as if something heats up internally in the tuner causing to go into a retune cycle. It gets worse as the transmission continues until it goes so far the TX just shuts down.

Is anyone else experiencing this problem?

My station consists of a TS480HX and the antenna is a Zero Five 1040 27 ft vertical fed by about 200 ft of 9913 coax.

It's worked very well until it started to have these problems a couple of months ago.

Any suggestions on how to fix this as it's getting bad enough to make the station unusable.

Thanks for your help!

Lloyd

Check the coax run, the radials at the antenna, the antenna itself, the balun or unun at the antenna, and the jumper from the radio to the tuner for any loose connections or signs of corrosion or shorts. That would be the first thing I would do. Maintenance and prevention every few months on these things are the most important to keep things good in the shack. If these all check out good, someone here might know of something else to help you.

Lloyd,

Sounds like a bad relay or inductor. They don't recover once they are stressed, it will probably have to be repaired.

I run a remote base as well. You'll find problems like this will drive you crazy.

It comes down to a tuner problem or an antenna problem (doh!). It is hard to prove if it is a tuner issue, so that leave the antenna (everything past the tuner).

I found investing in a Rig Expert http://www.rigexpert.com/index?s=aa54 worth every penny. About the same price as the MFJ stuff, but soo much better.

Since you can now sweep things with a picture, you can now have before and after pictures. A good tool to use to see what changed.

I have the AA 230 Pro as it has a built in TDR that is great for sweeping your feedlines.

Radio World stocks them.

Hi Mike --- A good analyzer is handy,I have an AIM 4170 which I like very much but I left it in Australia as I am thinking of getting a VNA.

The antenna is a Zero Five vertical at 27 ft making it non-resonant on any Ham band, so the VSWR will be high by design.

The strange part is this combination has worked well for almost 3 years and has only started to act up recently. I have one more thing to check before I rip into the tuner that could be the culprit.

I forgot that I have a gas tube lightning arrestor in line so I will check that out as these go bad at times and could cause the problem I'm experiencing. Just have get to the remote site.

Thanks for the suggestion and comments on the Rigexpert, they are a nice looking unit!

Cheers!

Good luck...

Where is your remote base?

Here is a posting from about 3 years ago on mine:
http://walkerphoto.blogspot.ca/2009/07/remote-ham-radio-operating.html.

This was before I installed the AT1000Pro on the LDG500 amp.

Wiggle the connectors when checking with an ohmeter to find intermittent connections (short or opens).

Sounds like current flow is likely heating things up look for cold solder joints or loose hardware. Remember the current is about 1.4 amps into a 50 ohm ideal load at 100 watt output(P=E x I) or (P=Esqr/R) or (P=I sqrXR)

Is there moisture condensation in anything ,what is your environment? dry wet etc

Check the coax run, the radials at the antenna, the antenna itself, the balun or unun at the antenna, and the jumper from the radio to the tuner for any loose connections or signs of corrosion or shorts. That would be the first thing I would do. Maintenance and prevention every few months on these things are the most important to keep things good in the shack. If these all check out good, someone here might know of something else to help you.

Subject: [LDG-auto-tuners] AT-600 Pro

I've been using an AT-600 PRO tuner at my remote HF station since the introduction of the tuner and it has worked well until recently.

Recently the tuner started to jump off it's tune point when using the TX. The tuner holds it's tune point at the start of the QSO but then starts to jump around as if something heats up internally in the tuner causing to go into a retune cycle. It gets worse as the transmission continues until it goes so far the TX just shuts down.

Is anyone else experiencing this problem?

My station consists of a TS480HX and the antenna is a Zero Five 1040 27 ft vertical fed by about 200 ft of 9913 coax.

It's worked very well until it started to have these problems a couple of months ago.

Any suggestions on how to fix this as it's getting bad enough to make the station unusable.

Thanks for your help!

From: shibukiau
Topic: 5585 Message: 5592

The problem has been identified and fixed!

When I finally managed to get to the remote station site, I found that the tuner had jumped to Ant port 2 whereas I had it set up to use Ant port 1, thinking that was the default position.

As a result it turned out that I was RX/TX'g through an open relay contact of the Ant selector relay K9 which still surprisingly allowed the tuner to tune my vertical to all of the bands as it had done, except for 80m where it started to object.

I did notice the signals to be down somewhat but I was able to hold QSO's as before but with some difficulty. I just wrongly assumed it was conditions.

As I continued to operate this way strange things started to happen as I described earlier, with the difficulty of tuning up on 80m showing up first.

In my configuration, Ant2 port was left open. I suppose if it had been loaded with even 50 ohms, it would have caused a much more noticeable difference in signal levels leading me to the cause earlier.

To avoid having this reoccurr, I am going to disable relay K9 and use Ant port 2, which is trhe depowered port.

Oh BTW, once I moved the ant coax to Ant port2, the tuner functioned normally, tuning even at 80m, the most challenging band for the tuner.

Thanks go out to all for your suggestions and particularly to Dwayne at LDG for his speedy response and provision of operational detail of the tuner.

Cheers!

I would like to know if other AT-600 Pro users experience this situation?

My Pro600 is connected to my Astron SS35M Supply (13.8vdc).

When I switch ON the Astron the AT-600 power comes ON and powers up .

When I than turn OFF (push LDG power button, LED goes out)) , and than turn off the Astron.

Here is what happens to my AT-600!

When the Astron is powered ON, the LDG Power comes back on!

I thought the tuner should remain OFF.????

Thanks ROB N8RT

The Chameleon Hybrid plus that 30 foot wire works beautifully on 80-6
meters. It does require a tuner and is rated to 1,500 watts.

http://www.chameleonantenna.com/ChameleonHybridSerie/ChameleonHybridSerie.ht
ml

I wish I had stock in Chameleon. Just use there products and am very happy
with them.

Hello Jimmy,

Thanks for letting me about the AT-600 Pro and AT200 acting just like I described!

Strange situation for powering up the tuner, but apparently others do the same!

Interesting that the AT1000 works differently, and more like I would expect!

My At600 Locks up occasionally, to the extent that NONE of front panel buttons work, and I have to UNPLUG the AT600 Power cord, and after reconnecting the power, all works as it should!

So I am trying to isolate the issue.

Thanks again for the info .

5597. AT-897 Construction Problems

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2012-08-21 02:03:06 UTC
From: dmaley88
Topic: 5597 Message: 5597

I purchased the LDG 897 tuner with the radio about six monthes ago. Seemed to be OK, but slow on some frequencies. Discovered reciently that it refused to tune anything on six meters. Not even a known good 10W microwave reject load scewed on to it.
Opened it up and found that all the internal RF jumpers and grounds were way too long and coiled up and a short piece of coax was also too long with a couple inches of bare center conductor on both ends.
I've shortened some of the grounds and RF jumpers. It now is happy with my 10W reject load on six meters. Wonder if anyone has a drawing on how this should have been done?
Also:
The internal SWR bridge is now just a hair out of balance. Anyone have the setup procedure for it?
Thanks in advance.

I had my AT-1000Pro lock up the other day as well. It required a power cycle of the tuner to get it back online.

It was an RF issue (hmmmm ... you'd think that a tuner would not have RF issues). I was in QSO and noticed that the meters weren't responding.

Watch out for the tuner jumping ant output ports Mike as this is what happened to me. Strange things happen then.

I fixed this by killing the power to the antenna selector relay K9 in the 600 Pro. From then on, at least for a week now, it's been sweet, performing like a charm!

Cheers!

when i push the tune button it tunes and the meter on the tuner says one thing and the radio says way different some times it swings over 3! could this be a grounding issue?

I have a four-month old AT-1000ProII and it locks up regularly, typically at least once a week. The power has to be removed completely from the unit in order for the microprocessor to reset. Once that is accomplished, it works nominally until, one day, when I go to press the tuner power button, nothing happens. Once again, I have to completely disconnect power before it will reboot.
Frankly, it's annoying and I'm not a pleased customer. I've tried both a wall-wart 12VDC supply and a dedicated 13.8 VDC linear supply. I've wrapped the DC power cable around a toroid to choke off any RF, all to no avail.
If anyone finds a solution to this vexing issue, please inform the group.

waldropgeorge:

Could be all kinds of things, so a bit more information would help.

Do you see the SWR swing while the tuner is tuning or after it's done tuning when you transmit normally?

Do you get some higher SWR on the radio when you use a dummy load on the output of the tuner?

Do you have other problems that might be stray RF when you transmit, such as messing up other equipment, noise is speakers, RF burns on your fingers?

Hello chuck i am not getting any rf burns are no rf showing in speakers are any thing like that when the tuner tunes it does it's normal thing and when its done it says 1to1 swr on the tuner then the radio says 1.5 swr which is ok but when i talk it jumps 2.5 are higher

Hello All,

Just a note that I am looking to purchase the remote control unit and cable for the LDG - RT 11 autotuner.

If you have one you want to sell please let me know.

I can be reached at 215-264-6737.

Thanks and 73,

Tim

Topic: 5603 Message: 5609

Chuck,

Those are all good things to look at. The one we have the most problems finding is the ground loop (or sometimes called circulating RF currents).

It mostly comes from RF getting into the ground system of the DC power supply. Since modern radios use DC ground and RF ground for the same thing, it's possible to get RF on the DC ground side of things. Then you can have an invisible mess.

Once you get RF on the ground, it can go to the radio, to the power supply, and to the tuner. Then back to the radio over the coax cable and just like that, we have a ground loop.

Just like pretty much all RFI problems, there is no single way to correct it. Some cases we've seen an isolator used on the coax line to keep RF from coming back down the coax ground.

Other times, its a snap on ferrite choke on the DC power cable to the tuner and one on DC power cable to the radio. If you have a tuner to radio interface, sometimes you may need one there.

Most times we never get other tell-tale signs of RF problems like buzzing in the speaker or RF burns. The circulating currents usually just go in circles and never get to other peripheral devices.

As you suggested, doing he dummy load test can help isolate the problem. Also lowering the RF power can help determine where the cause is. The technique is to lower the RF power until the problem goes away, make changes like adding RF chokes, then raise the power until the problem happens again. Then you know that you may need more chokes in that area.

I don't know of any way except trial and error to fix these types of things and they can get very frustrating.

Dwayne:

Whether there really is such a thing as a "ground loop" is probably a good item for discussion some day. Regardless, people clearly have problems with stray RF getting into things and causing problems.

I agree that solving this can be very frustrating, but I do think there's a way to approach this other than trial and error. The problem with stray RF and trial and error resolution is that you may solve the problem for one situation and then have it back again after changing bands or frequencies. It may also be that the kinds of solutions that are derived that way are also mutually exclusive--you can't manage to solve the problem for both of two specific frequencies.

I think the better approach is to decide where RF should be and where it shouldn't be, and avoid or fix the things that violate that. For sure, RF should be radiated at the antenna. Any means for RF to come back down the outside of the transmission line, by common-mode on open wire line, or on other control cables should be dealt with as standard practice. Transmission lines and other cables that are in the near-field of the antenna should either be placed so they are not likely to have power induced in them (i.e. transmission lines leave dipoles at a right angle) or should be broken up at least near the antenna and where they approach the house or shack by some type of reactance (such as line isolators, ferrite chokes, etc). Doing this not only reduces stray RF problems, but also reduces noise being conducted out to the antenna on the same lines.

If this is done as standard practice, the only problems you'll have is if the equipment is in the near field of the antenna and everything around it has induced stray RF. In that case, the only solution may be to place chokes on every cable entering equipment where there could be a problem. Also, equipment and all cabling should be built with good consistent shielding so that no stray RF has a means to leak into the equipment.

Chuck,

How is this: "In that case, the only solution may be to place chokes on every cable entering equipment where there could be a problem." any different than the trial and error method I suggested?

Please explain in detail how many chokes, where they go and what type would be used to solve ANY stray RF in the shack situation. Then explain the methodology of how you came up with those answers.

We suggest the trial and error method because there are simply too many variables with no two stations being set up exactly the same way. Lowering the RF power, making a change, checking for improvements, then raising the power (repeat, rinse) is the best overall strategy that we have found. Obviously I did not make this up, its in many books and articles about chasing down stray RF.

If you have a better way, thousands of other people that come across this issue will be all ears.

Dwayne:

You conveniently took a quote from the last portion of my comments on this and the one that's only related to the equipment being in the near field of the antenna. Even still, it's not a trial and error process to protect a each piece of equipment using good shield continuity and chokes. Also note that from the perspective of the equipment, cable connections to the equipment are a low-impedance point for common-mode energy and therefore don't require much reactance to effectively block that RF energy.

The key to what I was saying is that the RF should not even get to the shack. If that's unavoidable, and you're fully immersed in a strong RF field, then you need to fall back to blocking RF at the entry points to your equipment. That's a pretty straight forward process and is not trial and error. However, simply putting chokes on this line or that line, here or there, in an effort to get the stray RF under control is bound to be hit and miss and you'll likely have problems next week or next month or the next time you change frequencies, particularly if you try to equate the situation to "ground loops".

Yes, there is a better way and it starts by deciding where RF should be and where it should not be, then following standard and well defined practices to keep it that way. All ham stations have common attributes--they have antennas and they have equipment. That's a pretty clear distinction. Unfortunately, in the ranks of Hams there's way too much hyperbole and too many old wives tales distracting Hams from doing the right thing.

You're on the front lines of dealing with this problem because as people use tuners they get more power to their antennas and that results in more stray RF, so they naturally blame you and your equipment. I've seen that and sympathize with what you certainly must be doing in the way of support. But that's an opportunity to offer a straight-forward and consistent message to the many Hams you deal with.

If Hams are encouraged to engage in haphazard solutions, they will get exactly that.

It really sounds like the LDG tuner has not tuned.

Try this: Key (and hold) the radio mic in AM mode, press the tune button on the tuner for three seconds, then let go of the tuner button (keep the mic keyed). Let the tuner tune and when it's finished, unkey the radio. Then go to LSB or USB to check the SWR as you speak.

I operate a remote station and I use the LDG AT-200ProII and only use Ant port 1. Ant port 2 is empty.

I'm able to turn the power on and off for each of the devices in my remote station. Sometimes, whenever I power up, the antenna tuner switches to Ant 2 and the only way to switch back to Ant 1 is to drive 13 miles to the remote station and manually switch the AT-200ProII back to Ant 1.

QUESTION:

Is there any way to disable the antenna tuner from switching over to Ant 2? It seems to happen at the most inopportune time.

Thanks much!

dave :)

You may have missed my posts with the problems I had with my 600 PRO in a similar Remote application and my solution to it by disabling the internal antenna selector relay.

Fix is simple, cut the PCB trace to the antenna selector relay coil which in my case was K9. Then use the default antenna port which in my case was Ant2.

I still need to perform this surgery on my tuner but it is working well with the default antenna port. During the "surgery" I plan to jumper the antenna selector relay contacts to minimize future losses across it.

This should work for you too!

It's a great tuner when works!

Cheers!

Why not connect the antenna coax to both ports using a tee connector? You might encounter a small amount of loss from the tee but not much. That way you will always be connected and you don't really care if ant 1 or ant 2 is connected!

Hi -

I've been using an AT200 Pro 2 for three years now, very happy with its performance at remotely tuning an 88 ft center fed zepp on all bands.

But because I can't leave well enough along I've put one of old amps in-line, and will run about 500 watts out on 40 and 80 some when conditions are tough, and I'm trying to decide whether I need a 600 pro or a 1000 Pro?

Anyone had any bad luck with the 600 at appropriate power levels? The only bad experiences I've had with the 200 are infrequent plumes of smoke if its hunting under full load on a otugh match, and I've learned to approach those at lower power, and would do the same with the bigger tuner and more watts.

Thanks, Scott

You cannot tune with more than 150 watts or 100 watts if the SWR is over 3.0: 1 with the AT- 600Pro or AT-1000Pro. Tuning at full power would be very bad for the tuner. I run a 500 watt solid-state amp here but I only tune with 10 watts from my TS-590 after tuning is done I turn the amp on.

Lloyd

Good idea on killing the relay. I might do the same on my AT1000Pro and
add a switch to disable it if need be.

The other ideas are ok, but if you have never run a remote base, the 'mod'
you have to make has to be bullet proof, especially if you can't see the
indicators.

T-ing it might work, but I would have to look at the schematic to see what
is between the relay and the antenna connectors as part of the matching
unit.

Explain to me why Ant 2 would be the 'default?'. That was
a rhetorical question. :)

I run about 500 watts PEP out of an Ameritron AL-811 with no problems with my LDG-600PRO.

Subject: [LDG-auto-tuners] 600 Pro or 1000 Pro?

Hi -

I've been using an AT200 Pro 2 for three years now, very happy with its performance at remotely tuning an 88 ft center fed zepp on all bands.

But because I can't leave well enough along I've put one of old amps in-line, and will run about 500 watts out on 40 and 80 some when conditions are tough, and I'm trying to decide whether I need a 600 pro or a 1000 Pro?

Anyone had any bad luck with the 600 at appropriate power levels? The only bad experiences I've had with the 200 are infrequent plumes of smoke if its hunting under full load on a otugh match, and I've learned to approach those at lower power, and would do the same with the bigger tuner and more watts.

Thanks, Scott

Explain to me why Ant 2 would be the 'default?'. That was
a rhetorical question. :)

5632. Trouble with Z-11 Pro - RFI?

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2012-08-25 14:45:14 UTC
From: boris_the_bandit
Topic: 5632 Message: 5632

Hello all.

I recently bought a Z-11 pro from ebay, to replace my MFJ Versatuner.

I have an Icom 7200 and an FT-897, and my HF antenna is an off-centre-fed dipole (M0CVO HW-40HP), which can tune 80 to 6m bands with a little help. Both sets run 100w max, so should be fine with the Z-11 Pro.

The shack has an RF earth comprising two fair sized earth stakes, connected together and fed into the shack with a substantial copper welding earth cable. The two rigs and the Z-11 Pro are all earthed to this using equal lengths of coax, which have the centre and braid connected together at the "earth" end, and only the centre connected to the earth terminals on the equipment.

The tuner works fine at lower powers, but I have a problem on some bands from 20m up when I increase power (power level varies somewhat with band). The same problem is evident with a dummy load connected - but significantly more power is needed.

Observed problem is as follows: At low power, the tuner tunes and provides a good match. As power is increased, the SWR=1.5 light flickers (sound of a relay clicking lightly) - with a little more power the tuner kicks in, relays chattering away, and seems to get into a loop in which the SWR swings quite wildly, with the rig's protection system backing off the power on the SWR peaks.

On some bands this is easier to replicate than on others - on some, it seems to go straight into the tuning "loop", on others I can actually get a kind if "fizzing" noise just before the tuner cuts in.

Similar effects arise on both rigs, and I've swapped around the leads, removed the coax switch from the circuit, etc. to no avail.

I've rearranged the equipment to separate the various leads, I've tried RF chokes on either/both of the coax leads into the tuner, also on the power lead to the tuner, and I've also fed the tuner from a gel-cell to try and eliminate the problem - all to no apparent effect.

I realise the antenna isn't balanced, and that this might cause feeder radiation, but there is a coax "coil" (about 6 turns about 6" in diameter) some 10 feet below the feedpoint in an attempt to limit this.

I'm running a bit short of ideas - I can still operate fine on the bands I usually use, at my normal power levels (I seldom run "full chat") - but I'd like to get to the bottom of the problem.

Thoughts and suggestions welcome.

Many thanks,

Tony M (G4TRY)

Hello dear om,

do not use two cables for grounding. Use one groundcable and connect all the machines with the same lenght to an sartpoint where also the groundwire starts. OP use no grounding.

I use a AT-1000Pro antenna is a Zeppelinantenna 44 meter long with 450 ohm wiremancable 12 meters long into a balun 1:4, than another 20 Meters coax.
I run 400 Watts over the tuner with no problem.

Hello, Gernot, and thanks for the thoughts.

I may not have explained very well:

I originally ran the station with no separate RF earth, and had no significant difficulties with RF. Indeed, I ran it with the Z-11 Pro for a while also with no problem, but I was only using 40m and 30m, mainly cw and relatively low power.

However, the tuner makes it easy to switch bands, and I've recently been attempting to use higher frequency bands - and that was where the problem became evident

I put the earthing system in just a day or so ago, to try and cure the problem I described. The cable from the ground stakes comes into the shack, and connects to a terminal block under the radio bench. Each item of equipment is then earthed to the terminal block with its own earth lead - I think that's what you were suggesting. The individual coax earth leads to the terminal block are each 1m long, then there is about 1.5m of heavy lead going through the wall and to the first ground stake, then about 1m more heavy cable to the second ground stake.

Again, thanks for the reply.

Further suggestions welcome.

Boris:

I hate to be blunt, but there is no such thing as an RF earth (ground) whenever there's any significant length of conductors. This is particularly true on higher frequencies where the length of the conductors can be a significant portion of a wavelength or even multiple wavelengths.

The problem you have may be caused by stray RF coming from your antenna. That's not unusual with off-center fed antennas, even if they have a balun. You need to prevent RF from coming back down the transmission line (common-mode caused by imbalance at the feed point) using some type of coil or choke. If you're antenna is particularly close to your house and/or shack, then you may need to deal with RF induced on other conductors in and around your station.

That you have this problem also with a dummy load connected, although at higher power, may indicate some other issue, either with cable connectors or other types of leakage, or ...

While I don't have a Z-11 Pro, I do notice in pictures of the inside of this unit that the circuit-board ground plane for the non-RF sections of the tuner are isolated from the chassis ground, which is the RF section ground (jumper with ferrite choke on the board at the back near the ground terminal). You can see this near the upper-right of this picture.

http://upload.wikimedia.org/wikipedia/commons/thumb/a/a4/Ldg-antenna-tuner-0a.jpg/800px-Ldg-antenna-tuner-0a.jpg

I ran into a problem with this with another LDG tuner in that RF noise, was being conducted into the unit on the power and control leads and then being coupled into the RF section. Note that the control section of the tuner appears to have no RF ground connection to the chassis. I solved the problem on our tuner by replacing that choke with a straight jumper, which dropped our noise level by several S-Units.

If RF noise can get in this way, so would stray TX RF and that effect would be worse at higher frequencies. This may in fact be a reason why there's a recurring theme with LDG tuners and sensitivity to stray RF.

Chuck,

Thanks for the input - you raise some good points.

I've being doing some basic experimentation to investigate how the power I can run (without problems) varies across the bands. Initially, 80m, 40m 30m and 17m were OK - I could run 100W with no tuning problems, but on the other bands, only 50w or less.

On the basis that RF pick-up on the antenna feeder seems the most likely cause, I've been trying some RF chokes:

Putting a big clip-on ferrite with four turns of coax into the antenna lead just before the tuner fixed the performance on 15m, with no detriment elsewhere. Didn't seem to matter how many ferrites I used - I worked up to 6, with no additional benefits.

Then tried adding another choke outside, about 10ft below the antenna feedpoint (bottom of the aluminium pole, which is about 12 feet off the ground) - thought I'd fixed 20m, but turned out that was just because I'd left the (aluminium) ladder up - silly boy! With 3 ferrites below the antenna, 10m was OK at 100w - then I thought I'd try moving the choke down below the pole, rather than taping it alongside at the bottom - and now 10m is quite poor again.

The effect of the ladder on 20m raises the possibility of adding some wire to the bottom of the pole, vertically down towards the ground - although I haven't thought that one through yet.

I need to try a few other things - basically re-running the feedline so that it comes directly down to the ground, rather than coming into the house at the bottom of the pole - maybe another choke down there, with a direct ground to the braid, might help.

I also added the direct earth you suggested in the tuner itself, although that didn't seem to make any difference in my installation - good idea, nonetheless.

More work to be done - but not tonight!

Thanks again - further ideas welcome.

Best regards,

Tony M (G4TRY)

5637. Re: Trouble with Z-11 Pro - RFI? - NOW SORTED!

Topic: 5632 Message: 5637

Problem is now solved:

I've run a new feedline, this time remembering some of the basics I might have overlooked with the original (that I've used for over a year!).

1. Feedline now runs from the antenna straight to the ground - but well-removed from the aluminium mounting pole.

2. Feedline now runs round the outside of the house, at ground level, and straight into the shack - further from the antenna, much further from any domestic wiring.

3. Comes in through the wall, through two single-ferrite 4-turn chokes to the tuner.

In this configuration, I can run 100w on all the HF bands with no problem - only on the top 25% of the 50MHz band does the problem remain - and since this is mainly repeater outputs in the band plan, it isn't a concern to me - however, I still have the option of grounding the braid before the two ferrites, which might cure it. No great concern though - I reckon I've achieved what I set out to do.

Learning point: the LDG Z-11 Pro is very sensitive to RF in the shack - fix the RFI, fix the tuner.

Thanks to all for the constructive advice - much appreciated.

Best regards,

Tony M (G4TRY)

Hello all,

I recently purchased a z100 with the Yaesu One Touch Tuner Interface to go along with my FT-450AT.

According to the specs, the interface does not work with my radio, however, upon plugging it in, it does give the power necessary to run the tuner.

Is there something I can do to this to get it to work with my FT-450AT, or should I just plug it in to power and use it as a truly external tuner?

Thanks.

Radials are your friend. The more you put down, the better the vertical and tuning will work. A minimum of radials would be 12 spaced equally like the numbers on a clock face at least 34 feet long withe the 12, 3, 6, and 9 o'clock radials at 73.5 feet long. 12- North 3- East. 6- South. 9- west

See if this helps. Even just laying them on the ground without burying them will make a difference.

Thanks Joe,

I have 30-40 buried radials from 35 to 60 feet long. Buried radials don’t have any need to be related to wavelength as the ground effects detune them. There is very little directional effect from radials.

I’ve had the same radial field for 20 years and many different verticals operating successfully over that field on all bands including 160.

I appreciate your suggestions and interest.

Joe,

I thought a “43foot vertical with a 4:1 balun” was pretty explanatory. It’s home made with aluminum section 43 foot tall ground mounted and feed at the base with a 4:1 balun.

Which vertical are you using? Did you try a coil of your coax with four to six turns at the feed point of the antenna? There may be others with more suggestions especially after you list what vertical it is.

I tried... lol

Thanks Joe,

I have 30-40 buried radials from 35 to 60 feet long. Buried radials don’t have any need to be related to wavelength as the ground effects detune them. There is very little directional effect from radials.

I’ve had the same radial field for 20 years and many different verticals operating successfully over that field on all bands including 160.

I appreciate your suggestions and interest.

Subject: [LDG-auto-tuners] AT 1000 Pro on 43' Vertical

I just put up a 43' vertical with a 4:1 balun at the base and fed with about 75' of RG-213. The 1000 Pro is in the shack. I can tune the vertical on all bands except 80CW (80SSB tunes fine). It appears that there is not enough L available to tune these lower frequencies. I did try manual tunning and have max L in the circut. Anybody have any suggestions other than the obvious of switching in some external L.

Hi Bill,

The 4:1 balun is required due the high impedance at most frequencies of a 43' vertical. All commercial (and home brew) 43' have a 4:1 balun. Here a good page if you want to learn about them http://www.eham.net/articles/21272 . I have 30-40 buried radial of various lengths. The coax braid is connected to radial ground. The antenna works great on all but 80CW and 160.

Joe,

Mine is a copy of most of those. Again, all I looking for is any experience from 1000PRO users on tuning the 80 CW and 160 bands. The antenna works fine elsewhere.

Anyone with experience with the 1000pro on 43' verticals on 160 and 80CW, please let be know.

Bill,

I have a SteppIR BiggIR mounted near the 43'. They are electrically isolated though vacuum relays that open the radiators of the unused antenna. I've been doing some A/B testing on RX using the current NH8S DXpedition as my test signal. On 80 SSB, 40 and 15 they are equal. On 30, 20 and 17, the 43' hears significantly better and on 10 and 12, the SteppIR is significantly better. In all test cases, I have the 43' tuned though the LDG. My initial feeling is the high angle on 10/12 is a major drawback.

I really don't have a problem. What I'm really looking for is some feedback from others using the 1000 pro and a 43' antenna to confirm the tuner simple can't handle the high impedance on the low bands. The LDG tunes everywhere else just great. I may try to put my big old manual tuner in and see how that works.

With the SteppIR, I have 80 covered and I have a 160 loading coil I can switch in on the 43' and that plays perfectly. I'm trying to see if I can do it all with one 43' with just a tuner in the shack for the future when we may move to a smaller location.

Thanks for the interest.

Hi Gerry,

Just a thought, but I used to have an 80m inverted L setup, and 43' is approaching 3/16ths (only 1/16th of a wavelength away from a 1/4 wave) of a wavelength on 80Instead of having a high impedance antenna that's too long, you're more likely to have a low impedance antenna that's too short. Have you tried removing the balun and seeing if it will tune on the low band? You might find that instead of being too high impedance, that it's actually a low impedance at that particular frequency, and that the 4:1 balun is taking that beyond the lower range of the tuner?

You've also got other things to consider, as you WILL have standing waves on the coax, which WILL play havock with the SWR/Impedance that the tuner sees depending on the length of the coax. Have you tried adding/removing a few feet of coax between the tuner & antenna and seeing if your results change?

Cheers,
Josh

My take of it is that when you are down the CW end of the band on 80, the 43 foot antenna would have a very low impedeance and by connecting a 4 to 1 balun so that you have 50ohms side at the tuner and 200 ohms at the antenna side (in theory) if for instance you had already low impedance at the bottom of the antenna the input of the antenna tuner would actually be seeing one quarter of that impedance.

Thats my take on it

Hi Josh,

I will try your suggestion of changing the coax length and see what happens. I don't expect that's the issue. What I really want to find out is if the 1000pro has the range to tune the 43' on the lowest bands. If not, I may play with other changes. Clearly the 1000pro can tune the 43' at 3.8 but not at 3.5 mhz. I just tried it at 3.6 and no tune. At 3.65 I got a tuning solution.

I'm sure I could get it to play fine on the low bands by making loading/matching changes at the antenna. This would no doubt also cause unwanted changes on the higher bands that now work fine. What I want is to fine a tuning solution for all bands from the shack. I'll put a big old Pi manual tuner in line tomorrow and see what happens.

Thanks for the interest,

Topic: 5640 Message: 5655

Hi Tony,

These antennas have been around forever and have always used a 4:1 at the base (in truth 1:4) as the 1: side is to the coax. The problem (I think) is the range of the tuner. It appears the L network tuner in the 1000pro has all the L out and and all the C in when it has a tuning solution at the edge of it's range (3.65 mhz).

You are right on the impedance being to low on the low bands. It would make one think that the Balun is backwards for the low bands but the impedance gets quite high on the high bands so it's all a compromise.

I fun project for sure.

Thanks for the suggestions.

Subject: Re: [LDG-auto-tuners] AT 1000 Pro on 43' Vertical

My take of it is that when you are down the CW end of the band on 80, the
43 foot antenna would have a very low impedeance and by connecting a 4 to 1
balun so that you have 50ohms side at the tuner and 200 ohms at the antenna
side (in theory) if for instance you had already low impedance at the
bottom of the antenna the input of the antenna tuner would actually be
seeing one quarter of that impedance.

Thats my take on it

Hi Gerry,

What's most likely to have happened is you've hit a low impedance point on the feed line, altering the feed line should resolve these issues.

When dealing with a remote, non-resonant coax-fed antenna you CANNOT think of the coax as presenting the same impedance to the transmitter all the way along. The standing waves on the Coax that are caused by the impedance mismatch will transform the impedance of the antenna depending on the length of the coax. If you've hit one of these points, you'll find that you're Often altering the coax a little longer or shorter can resolve these issues, as it will change the impedance that the tuner will see by just enough that it will allow you to tune.

Cheers,
Josh

> What I'm really looking for is some feedback from others using the 1000 pro and a 43' antenna to confirm the tuner simple can't handle the high impedance on the low bands. The LDG tunes everywhere else just great. I may try to put my big old manual tuner in and see how that works.

Whenever I have used an antenna that is a compromise (i.e. wrong length, lack of radials, etc) and it doesn't tune I try adding a length of coax to the feed-line. My guess on 80CW would be 25-50 feet. Sometimes this is enough to change the feed-point characteristics to something that the antenna tuner can deal with. This is not the best fix, but sometimes it gets you on the air with little effort. I haven't tried this on the typical 43' vertical but it may work.

I've never had good luck in moving an HF antenna from one location to another and have it work the same. Too many location variables......

5659. Ldg 600 pro autotuner issue

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2012-09-11 12:59:26 UTC
From: mcyman
Topic: 5659 Message: 5659

Hello all, I am still having an issue with my LDG600Pro,

The problem manifests itself as follows.

My tuner is connected to a Astron 35 amp power supply.
When the Astron is first turned on the LDG immediately powers up, at this point I can turn the LDG on or off the power switch works as it should.
I than turn OFF the LDG, Bypass the tuner!

I occasionally use the tuner when I use my Kpa500 (Elecraft) 500 Watt amp.

This last week I made a few contacts without using the amp.

Here is what happens with everything still powered up and working!

When I pushed the LDG600 Power button, NOTHING happened! The 600 pro would not POWER up!

The only way I could get the 600 Pro to power up, and work as it should, I had to physically remove the DC Power cord on the back of the LDG tuner, and than reconnect the plug to the 600 pro.

Somehow the 600 pro LOCKS up. Just running 100 watts out of my Kenwood
TS590, when the 600 pro tuner is OFF.(By PAssed)

Wonder if any one else has had this issue, and if so , how did you correct the problem?

thanks Rob N8RT

> What I'm really looking for is some feedback from others using the 1000 pro and a 43' antenna to confirm the tuner simple can't handle the high impedance on the low bands. The LDG tunes everywhere else just great. I may try to put my big old manual tuner in and see how that works.

Whenever I have used an antenna that is a compromise (i.e. wrong
length, lack of radials, etc) and it doesn't tune I try adding a length
of coax to the feed-line. My guess on 80CW would be 25-50 feet.
Sometimes this is enough to change the feed-point characteristics to
something that the antenna tuner can deal with. This is not the best
fix, but sometimes it gets you on the air with little effort. I haven't
tried this on the typical 43' vertical but it may work.
>
> With the SteppIR, I have 80 covered and I have a 160 loading coil I can switch in on the 43' and that plays perfectly. I'm trying to see if I can do it all with one 43' with just a tuner in the shack for the future when we may move to a smaller location.
>
>

I've never had good luck in moving an HF antenna from one location to
another and have it work the same. Too many location variables......

I've NEVER heard of a ground mounted vertical being a "BALANCED"
antenna. Why would you use a 4/1 BALANCED to UNBALANCED transformer at
the base of such an antenna?

A 4/1 impedance transformer with the higher impedance side on the coax
side, MIGHT be appropriate, because I'd betcha a donut to a dollar that
the impedance presented @ 3500 KHz would be rather low.

The "ideal" place for the matching device, such as a the LDG is at the
base of the antenna, so the coax is looking at 50 ohms resistive or
close, and there's no extra loss. I've never used 43' vertical, but I
do know that a coil (now a daze called an "inductor") made of
approximately 31' of wire wound on a 2" plastic pipe really "tames" a
31' vertical so it can be matched by a LDG Z-100 tuner placed at its base.

Thanks Hank,

It’s configured as a UNUN as per DX Engineering’s documentation.

As per my previous post, it all works fine now with the addition of some coax.

Why not simply leave the tuner on all of the time after it's been powered-up by the Astron? You can bypass the tuner by pushing the "Tune" button quickly. That's how I run mine and I've never had an issue.

Subject: [LDG-auto-tuners] Ldg 600 pro autotuner issue

Hello all, I am still having an issue with my LDG600Pro,

The problem manifests itself as follows.

My tuner is connected to a Astron 35 amp power supply.
When the Astron is first turned on the LDG immediately powers up, at this point I can turn the LDG on or off the power switch works as it should.
I than turn OFF the LDG, Bypass the tuner!

I occasionally use the tuner when I use my Kpa500 (Elecraft) 500 Watt amp.

This last week I made a few contacts without using the amp.

Here is what happens with everything still powered up and working!

When I pushed the LDG600 Power button, NOTHING happened! The 600 pro would not POWER up!

The only way I could get the 600 Pro to power up, and work as it should, I had to physically remove the DC Power cord on the back of the LDG tuner, and than reconnect the plug to the 600 pro.

Somehow the 600 pro LOCKS up. Just running 100 watts out of my Kenwood TS590, when the 600 pro tuner is OFF.(By PAssed)

Wonder if any one else has had this issue, and if so , how did you correct the problem?

thanks Rob N8RT

40'. Wow! That's heaps. On a non-resonant system I'd recommend reducing
that length, as your losses will be pretty high. You probably only needed
to add 1-2 feet of coax to solve the problem.

Josh,

It was just what I had handy and it proved the solution. I don't really use the 43' with the UNUN on the low bands. My SteppIR is great on 40 & 80 and supper on the high bands. The 43' is better on 15, 17 and 20 and it works fine there without the extra coax. I do use the 43' on 160 where I switch in an old Butternut 160 base loading coil.

More trying to prove that the 43' would work should we move and I can only put up one antenna. In that case, I'd get a new tuner and put it at the base. Based on 10/12 performance, I might play with a shorter version as well.

Hi Gerry,

For a vertical antenna like this, a remote tuner at the base is definitely a much better way to go. You could do away with the un-un as most remote tuners will handle fairly high impedances. Good to hear you got it working!

I actually use a similar transmission line trick with my balanced line fed doublet. As the antenna is non-resonant on any of the HAM bands I actually take advantage of the standing waves on the ladder line so that my tuner can tune the antenna on all bands. The advantage here of running a doublet and ladder line however, is that the losses are significantly less than that of coax as it's a balanced feed system.

Cheers,
Josh

I don't think 1-2 feet would do it at 3.5MHz. 40 feet of RG8, assuming
it has a velocity factor of 66%, would be equal to about 60 electrical
feet. That would be almost a quarter wave at 3.5MHz.

Joe

I've been using one of those in Dubai for the last few years called a G5RV. Can't believe how well it work even considering the A6 call. Even worked back here on 40 with 100 watts.

Thanks for the advise. I sure learned a lot more about 43' verticals.

40ft of Belden 9913 (RG8) would provide .4 DB loss at 3.5Mhz. That is probably the reason it work. You just needed that little extra return loss to fool the tuner into thinking it was within range.

Hi Joe,

The thing here is though, we don't *need* to shift by a full 90 degrees. In order to move off the extremely low/high impedance effect that the standing waves on the coax at the frequency in question are causing, we only need to move by a few degrees, hence, a few feet should do the trick.

When feeding a non-resonant vertical with coax, it's very similar to choosing "random wire" lengths. You don't want certain multiples of a wavelength +- 5%, or the transformation effect from the standing waves on the transmission line will cause exactly this effect. To get away from that effect you only need to alter the line length by a very small amount.

Cheers,
Josh

Hi Leonard,

This is true, IF the antenna is resonant and there are no standing waves on the coax. When non-resonant, the losses are much, much higher.

Cheers,
Josh

Actually know. That number was looking at coax and SWR loss.

What load SWR did you have entered?

I'm pretty sure a 43 foot vertical on 3.5Mhz is going to have a fairly high SWR

Topic: 5640 Message: 5678

I stand corrected, at that particular SWR the loss value is correct.

You would need to punch in the antenna in to a simulator to figure out the actual SWR on the line however, and re-run the numbers.

The point still stands however, that as the SWR goes up and the tuner "matches" the antenna at the end of a coax feed line, the losses do go up, and it's not uncommon for the SWR at the feedpoint of a non resonant antenna to exceed 10:1

From: Leonard K. Pennock
Topic: 5640 Message: 5679

I agree with you. In fact I should probably have used around 11-12:1.
Reason is that he is able to match most of the 80m band with the tuner.
The tuner is rated at 10:1 so he was just outside the range of the
tuner. Plugging in 11:1 on the coax calculator yields 0.4798DB total
cable loss. 11:1 SWR has a return loss of 1.584db on the VSWR
calculator. Changing that return loss to 2.063db gives an effective SWR
of 8.5:1 which is well within the tuners range.

Topic: 5640 Message: 5680

Ah yes, but you're not taking into account the fact that depending on the transmission line length, and the interaction of the standing waves on the line that the "apparent" SWR will change depending on the transmission line length. The only way to accurately calculate the loss is to know what the impedance/SWR is *at the feed point*. Depending on the length of the coax line the "apparent" SWR will change, and infact this is exactly what adding the coax to the feedline has done - altered the interaction of the standing waves on the coax line, and brought the "apparent" SWR into range of the tuner.

True, but a 1-2 foot jumper would give you less than 1 degree shift.
Probably not enough. His 40 foot jumper is probably excessive, but it
works. I never argue with success.

I have the exact same problem. I use the 600 pro and shut it off but the power supply stays pluged in. The next morning I turn the 600 pro on and it is dead. I unplug the power supply for a short time and plug it back in and the 600 pro turns on. I e-mailed LDG and they said they are working on this issue. Dale (N2AVO)

Subject: [LDG-auto-tuners] Ldg 600 pro autotuner issue

Hello all, I am still having an issue with my LDG600Pro,

The problem manifests itself as follows.

My tuner is connected to a Astron 35 amp power supply.

When the Astron is first turned on the LDG immediately powers up, at this point I can turn the LDG on or off the power switch works as it should.

I than turn OFF the LDG, Bypass the tuner!

I occasionally use the tuner when I use my Kpa500 (Elecraft) 500 Watt amp.

This last week I made a few contacts without using the amp.

Here is what happens with everything still powered up and working!

When I pushed the LDG600 Power button, NOTHING happened! The 600 pro would not POWER up!

The only way I could get the 600 Pro to power up, and work as it should, I had to physically remove the DC Power cord on the back of the LDG tuner, and than reconnect the plug to the 600 pro.

Somehow the 600 pro LOCKS up. Just running 100 watts out of my Kenwood

TS590, when the 600 pro tuner is OFF.(By PAssed)

Wonder if any one else has had this issue, and if so , how did you correct the problem?

thanks Rob N8RT

Perhaps you should press the TUNE button briefly to put the tuner into 'Bypass' mode first (little red led on) before you turn off the power. I'm kinda' thinking that it's still in the 'TUNE' mode when you shut it off and the latch relays are still locked on the previously tuned frequency. Mine is connected to an Icom IC-706MKIIG and powers up/down whenever I turn the radio on/off and I don't have the issue you speak of.

As I indicated in my post a few weeks ago, I am experiencing exactly the same issue with my AT-1000ProII auto tuner. My current work around is that I have the tuner connected to a small 13.8 VDC power supply dedicated only for use with the tuner. When the tuner power button fails to operate, I reach over and flip the power supply off and back on, saving me having to physically remove the DC power cable from the back of the tuner.
This issue appears to be systemic and appears to affect the 600Pro and the 1000ProII. I hope LDG will get to the bottom of it quickly and let us all know what is happening and how to resolve it.

Vince

Vince or anyone else having this issue with an AT-600Pro or AT-1000ProII, please contact us directly with your mailing address. It seems that we may have had a batch of processors that does not like to be turned on and off a lot.

We'll be happy to send you a new processor.

Dwayne:
Thank you for your quick reply. I have emailed you separately with my mailing address. I am wondering just what is involved in replacing the processor. I presume full instructions will come in the mailing. Thanks again, I am sure numerous owners will be in touch with you.

I know the LDG is fine, but this video shows nothing. The LDG will tune a lot of poor antennas, and this may be just a good example. Do you have something that shows something about the antenna?

Hello,
I am new to this group but i have a question,
I boughtan At200proII with the y-cable to complete my ft-857D. In the manual is stated that with the y-cable the radio will power down and switches to cw mode. This doesn't happen an yes the cable is in the right way binstalled. The tuner tunes and the radio switches to tx but doesn't switch to cw or power down. Any Ideas?

When you push the tune button on the tuner the radio should send a
carrier; however, it will be at the current power setting of the radio.
It doesn't reduce power other the fold back circuit when the SWR is high.

I am new to this group but i have a question,
I boughtan At200proII with the y-cable to complete my ft-857D. In the manual is stated that with the y-cable the radio will power down and switches to cw mode. This doesn't happen an yes the cable is in the right way binstalled. The tuner tunes and the radio switches to tx but doesn't switch to cw or power down. Any Ideas?

I also, have the Chameleon Zepp, the older one. It will handle , I believe, 500 watts, and tune 80m to 6m. I have used it indoors with some success. The matching section is 25 feet and the resonator section is 50 feet.

This EHAM review is typical, and describes nothing. The first part is an ad
and has things like "Polarization: Linear" and the claim that it can be
mounted anywhere, anyway. (But, it says: the SWR depends on how it's
mounted, even though it claims to have a 50 Ohm impedance)
Does anyone have a description of the Chameleon?

5697. Z-11 Pro II Green light just flashes

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2012-09-17 06:59:42 UTC
From: Jeremiah Norrell
Topic: 5697 Message: 5697

I have been Using the Z-11 Pro for about a week now. Everything has been fine. I guess I should mention I have been using it with a Icom 706-mkII and a G5RV. I have used the tuner to tune 10-80 meters just fine. Tonight when I went to work some PSK I noticed the green 1.5 light just flashes continuously. I dont think it will tune on 80 anymore. Any ideas what that light means?

Hi!
If anyone is interested, I have listed my nearly new leg z-11 pro II for sale on eBay. The item number is 140853950634.
Asking $140.

Works well...just realized I prefer a manual tuner.

From: Michael Walker
Topic: 5699 Message: 5703

I have 2 of these tuners and each are problematic.

Both hang requiring a full power off to recover. Since I use both of these on my remote base, I have to be able to trust their configuration. They are not a problem if they are sitting on a desk in front of you.

Other than that they work perfectly with my amplifiers (SGC500 and Acom A1000). The A1000 is connected to my Windom. Again, they work perfectly as a tuner.

Hence, I am selling them both $450 each plus some shipping costs. I can be reached offline please.

Although not my primary use, I've been wondering if I could use my LDG AT-100 ProII with a CB radio (in full auto mode of course)? Will those frequencies outside the ham bands be accepted? I occasionally like to use those channels, and have a 31 foot tall vertical that I use for 40-6 meters.

Thanks,

Gene KC9WFW

AT100Pro and Z11Pro had no issues outside the ham bands so I doubt the
AT100ProII would.

5709. AT-600 Pro on 6 Meters

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2012-09-29 13:04:06 UTC
From: w3iaxftvfd
Topic: 5709 Message: 5709

I have a new AT-600 Pro we aare using with an Icom 756 Pro and Elecraft KPA500 amplifier. I am still learning the AT600, so far so good except it isn't happy on 6 meters and when discussing with a friend about his AT1000 on 6 meters, he is seeing same annomolies.

I am using a Cushcraft 5 element beam with a gamma match. This antenna really shouldn't even need a tuner on 6 meters, however when using the AT600 Pro it tunes, BUT when you transmit it reduces power from 100 watts to about 30 watts. Also with my 270 ft OCFD which tunes nicely, power in transmit is reduced.

For now when operating 6 meters, I disconnect power to the AT600 and use it as a "jumper". What am I missing or is this a defect or a design flaw ??

Thanks in advance,
Bob, W3IAX

Bob--
It sounds to me like the match from the 756 to the Amp is off. The power reduction is within the 756, isn't it? How is the match from the 756 to the Amp done?

Subject: [LDG-auto-tuners] AT-600 Pro on 6 Meters

I have a new AT-600 Pro we aare using with an Icom 756 Pro and Elecraft KPA500 amplifier. I am still learning the AT600, so far so good except it isn't happy on 6 meters and when discussing with a friend about his AT1000 on 6 meters, he is seeing same annomolies.

I am using a Cushcraft 5 element beam with a gamma match. This antenna really shouldn't even need a tuner on 6 meters, however when using the AT600 Pro it tunes, BUT when you transmit it reduces power from 100 watts to about 30 watts. Also with my 270 ft OCFD which tunes nicely, power in transmit is reduced.

For now when operating 6 meters, I disconnect power to the AT600 and use it as a "jumper". What am I missing or is this a defect or a design flaw ??

Thanks in advance,
Bob, W3IAX

Bill, the Elecraft amp works fine and can be turned off. The problem is the AT-600Pro acts like it doesn't like 6 meters. Regardless whatever I do as long as power is applied to the AT600 on 6meters it reduces the 756 power output. The only way I can operate 6 meters is to physically pull the input power connector to the AT600 to force it to be a "jumper". Even with the AT600 in "Bypass" mode.

Also I learned that antenna 2 is the default and labelling in the Instruction Manual is in correct.

Bob--
Sorry-- ignorance on my part. I did not realize that the AT provided control feedback "around" the Amp, to the 756.
Good luck--Bill--W4BSG

Has any one hav trouble the antenna so239 coming loose.

I found it was lose the nut on the inside came and took out my

Yeasu ft-897d I had to send my radio pack to yeasu because no alc or

power out put. so watch you turner I like it but I found my ft-100

did the same thing. and the whole on the sub d is cut wrong and I had

too round out the whole to make the cable to fit to get it to work.

Just tell the group watch the coax so-239 will come loose. and hav no ground.

Gary,

Yes, it's possible for the nut to come loose on the SO-239 for that tuner. It should be checked any time the tuner is shipped as it may come loose. A good time to check it is when you have the lid off the tuner to install on the side of an FT-897.

It's unlikely that the loose nut caused the radio to go out (but not saying impossible). The radio has a protective circuit that automatically lowers the RF power when a bad match is presented to the radio.

With that being said, the radio's protective circuit may not have been working properly and failed to protect the radio when the nut came loose on the tuner.

Better check your settings on the Z-11. I have a Z-100 which lasts considerably longer than that - weeks when I forget to unplug it between contests. I usually operate at least one contest a month, so it's rare that I find that I've left it on for more than a month at a time, but, it will work for quite a few more contests after a month of being on 24/7.

My first set lasted a year. The set in there now is about 2 years old. I'm a pretty casual op though. But one week? That sounds wrong, no matter how much you are tuning.

From: n0nzg
Topic: 5720 Message: 5720

I have a ts-480 sat and I am some what disappointed in the performance of the internal tuner. It has a very narrow range compared to the tuner in my ts-570d. I do have a long forgotten Z-11 Pro tuner sitting on the shelf that I would like to use as an external solution to this problem as most of my portable set-ups need a wide range tuner to work correctly. How can I interface this to my TS-480 SAT and have ether the tune button on the radio or tuner work to start an auto tune cycle.

Thanks,

Jeremy N0NZG

5721. LDG IT-100 LED Blinks 4 times

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2012-10-21 03:28:24 UTC
From: Brad
Topic: 5721 Message: 5721

I just bought the LDG IT-100 about a month ago and it has been working fine with my IC-7000. I've been busy at work and here at home but have had time to make several short contacts on HF using the Tuner. Today, the tuner began to act differently than before.

My brother just got his HF antenna up and we started searching for a good HF frequency to use. After tuning on a couple of different bands, the tuner stopped making the "clacking" noise during tune and I started getting 4 LED blinks after "Tune" and no green SWR LED like I used to get. 4 blinks means the tuning cycle failed, no RF was detected.

My SWR meter was reading 1.0 on transmit but my brother could not hear me.

I turned everything off, completely disconnected power, reconnected power and turned the radio back on. I then put the Tuner into bypass mode then back into active. Then I pressed and held the Tune button on the face of the tuner until the red LED came on and then went back off (put the tuner into "Full Tune" cycle).

The familiar "Clacking" sound started again and I got a green SWR light. I then transmitted and was able to talk to my brother on 80 meters. Life was good.

We decided to switch to 40 meters due to noise on 80 meters. I hit the "Tune" button on my microphone but got the 4 LED blinks again with no "Clacking" sound. Uh oh.

I tried again all the things I had done previously but this time nothing seems to work.

I'm new on HF and I am inexperienced in the use of tuners. I have attempted to follow the manual in the setup and I have tried the things suggested in the manual but I'm quickly at a loss for what to try now. Is this an indication of a problem with the tuner or is it possible I have something else going on that I need to figure out? I'm open for ideas.

Thanks!
Brad (AK4RE)

5722. YT-450 compatible with other radios?

Just send some RF to the tuner and it will automatically tune. You really don't need the tune button.

Yes, the Z11 is a tuner while the internal ATU for the 480 is an antenna matching unit. Less range.

This is on their web site:

he Z-11ProII has 2,000 memories automatically storing tuning configurations for each frequency and band as you use them. Frequency sensing circuitry lets the Z-11Pro ?know? your operating band and frequency. Whenever you transmit on or near a frequency you?ve used before, the Z-11ProII retunes from memory almost instantly. Full auto mode tunes with SSB. Just speak into the mic and it tunes! Memories are retained indefinitely.

Topic: 5725 Message: 5725

Hi All,

If you have an AT-11 V2.5 board from the late 1998 to 2001 time-frame, we have 10 SPK20 boards left over from this long-forgotten project. The SPK20 board added a number of audible beeps to the AT-11 to give you an audio indication of the final match that it found. 1 beep was good, 5 beeps was worse.

These boards are assembled, but missing the flat speaker, the LM386 chip, and the wires that goes to J4 on the AT-11 2.5 PCB.

The unit uses a low pass filter and LM386 chip to provide the beeps from inside the enclosure once a tune has been completed. These only work on AT-11 units and only version 2.5 PC board.

The first 10 people that respond on this list will get one and then they are gone forever.

Hi Group,

Somehow, we ended up with 40 extra battery holders for the Z-11ProII. We probably ordered a couple to test with, but got too many. Anyway, you can get a 4-AA holder that will fit in the Z-11ProII for $5 shipping included to US and Canada.

To get one, go to our web site under Support/Manual on the left side, then click Tech Support in the middle of the page, then scroll to the bottom to the PayPay button. Type in Z-11ProII Battery Holder and then press the Pay Now button. There is no need to contact us first as we already know this is going on.

Ronny:
That tuner is specifically designed to work only with the 450 and 950 transceivers. when you press TUNE it 'talks' to those rigs and changes them to AM mode and low power, tunes, and then switches the rig back to whatever mode you were on when you pressed TUNE. It is not intended for any other rigs.

Guess it will be off to eBay then. I have it listed on QRZ and no one
wants it. Thanks for the info. I thought it would work like a Z-100
and do a tune based on what it was "seeing" from both the rig and antenna.

Ronny and Julian--
As far as I know, it WILL work independently, with most rigs. It's just that the convenience features (Tune button) don't help.
I have an FT-950; what are you asking?

Guess it will be off to eBay then. I have it listed on QRZ and no one wants it. Thanks for the info. I thought it would work like a Z-100 and do a tune based on what it was "seeing" from both the rig and antenna.

5732. SPK-20 boards

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2012-10-23 12:19:32 UTC
From: Tony Brignole
Topic: 5732 Message: 5732

I would like one of the SPK-20 boards if possible.

Please advise cost etc.

I have an older AT-11 which works great but haven't opened it to see version.

Subject: [LDG-auto-tuners] "Wayback Machine" for the AT-11

Hi All,

If you have an AT-11 V2.5 board from the late 1998 to 2001 time-frame, we have 10 SPK20 boards left over from this long-forgotten project. The SPK20 board added a number of audible beeps to the AT-11 to give you an audio indication of the final match that it found. 1 beep was good, 5 beeps was worse.

These boards are assembled, but missing the flat speaker, the LM386 chip, and the wires that goes to J4 on the AT-11 2.5 PCB.

The unit uses a low pass filter and LM386 chip to provide the beeps from inside the enclosure once a tune has been completed. These only work on AT-11 units and only version 2.5 PC board.

The first 10 people that respond on this list will get one and then they are gone forever.

Brad,

It's a long shot, but you may have a bad RF jumper cable between the tuner and radio.

Jeremy,

There is no way to interface the Z-11Pro to the TS-480. However, you can program the PF key to send a 25 watt carrier and leave the tuner in Auto mode.

Then when you press the PF button, the radio will send a carrier and the tuner will sense that and tune. Once the tuner is finished, press the PF key again and the radio will un-key and return to the original mode and power level.

Be sure to turn off the internal tuner in the TS-480SAT.

Hi Brad

Did you switch to low power 10 watts and use a cw mode or other continuous output for tuning and key your mike until the tuner green led lights especially if your on a new band.

Did you by chance read the LDG operating manual and try a manual tune

Maybe your antenna is outside the tuner capabilities.

Site conditions do impact the generalized theory,closeness to ground,object near the antenna that are grounded e.g. wire fences etc, metal house siding,stucco wire,wire too close to the tower e.g. sloper (approx 3 feet away) .

Elaborate more and the answers can become less general

bill's reply questions are the first things one would ask not knowing your antenna system,radio etc

The other resource is Dwayne on this forum from LDG.

Subject: [LDG-auto-tuners] LDG IT-100 LED Blinks 4 times

I just bought the LDG IT-100 about a month ago and it has been working fine with my IC-7000. I've been busy at work and here at home but have had time to make several short contacts on HF using the Tuner. Today, the tuner began to act differently than before.

My brother just got his HF antenna up and we started searching for a good HF frequency to use. After tuning on a couple of different bands, the tuner stopped making the "clacking" noise during tune and I started getting 4 LED blinks after "Tune" and no green SWR LED like I used to get. 4 blinks means the tuning cycle failed, no RF was detected.

My SWR meter was reading 1.0 on transmit but my brother could not hear me.

I turned everything off, completely disconnected power, reconnected power and turned the radio back on. I then put the Tuner into bypass mode then back into active. Then I pressed and held the Tune button on the face of the tuner until the red LED came on and then went back off (put the tuner into "Full Tune" cycle).

The familiar "Clacking" sound started again and I got a green SWR light. I then transmitted and was able to talk to my brother on 80 meters. Life was good.

We decided to switch to 40 meters due to noise on 80 meters. I hit the "Tune" button on my microphone but got the 4 LED blinks again with no "Clacking" sound. Uh oh.

I tried again all the things I had done previously but this time nothing seems to work.

I'm new on HF and I am inexperienced in the use of tuners. I have attempted to follow the manual in the setup and I have tried the things suggested in the manual but I'm quickly at a loss for what to try now. Is this an indication of a problem with the tuner or is it possible I have something else going on that I need to figure out? I'm open for ideas.

Thanks!
Brad (AK4RE)

From: Ken
Topic: 5720 Message: 5744

I use a programed PF button on my TS-590. The RF Sense in the Z11 pro always works fine. The Z11 pro does not need much power for tuning up.. It should work with 5 watts (or even a lower power).. considering it works with with QRP rigs like the FT-817. I use mine set to 10 watts but the reason for this is that the MFJ-993B, on my radio's other antenna port, will not work with less power.

Follow up after changing the Processor chip in the AT-600 Pro.

Thanks LDG for the new later date processor trying to resolve the,
600 from locking up!

However the new processor did not fix my problem.

I have a separate power supply connected to the AT600, when the power supply is first turned on, the AT-600 powers up ,LED power light comes on.
I than press the AT600 power button, which turns off the AT-600 and by passes the AT600 to Ant 2.

I than use my Kenwood TS-590 running about 100 watts, on SSB or CW for any period of time.

I than decide to power up the AT600, by pressing the AT600 power.

Nothing happens the AT600 will not respond and is LOCKED UP, the only way to bring the AT600 back to use is to unplug the Power COrd on the back of the AT600, and re insert the DC plug.

Or I can turn off the AT=600 DC Power Supply and the turn it back on and again the AT600 powers up as it should, and WORKS, as it should!

In my OPINION, I be-leave that when the AT600 is Powered OFF and RF is passing through the AT600, RF is causing the Processor to loose control of the Power Switch!

I have read others have experienced this issue, and I am not sure how to correct the problem.
I am happy with the tuner except for this issue

I would rather think the rf would be getting in via the power cable but
like you that's just my opinion. Try filtering the power, a different
power supply (like a battery closely coupled, just for testing) etc.

Jim.

Beat me to the punch. I was going to recommend putting a ferrite on the
power lead with power lead making a couple wraps on the core.

Question why are you powering off the tuner after you initially power it on maybe incorrect operator error is the issue

some other areas you have maybe not thought of to go looking

What happens when the tuner and radio are on the same power source?

Some of today's electronic is much more susceptible to rf/emi interference.

How clean is the emi/rfi profile of your external dc power supply on both the ac and dc leads?

Is it a brick wall wart style you are using?

Have you use an oscilloscope and checked how pure the dc actually is?
.
You may get a surprise on how poor the DC is out of some power supply designs? a recent issue of CQ did test a number of dc power supplies.

Is there small levels of RF appearing on your ac power cord.

Are both supplies on the same ac circuit breaker in your electrical panel.the ac wiring will migrate problems.

I looked at the dc power leads of my Kenwood TS50 and saw the amount of noise going back to the battery and added some rf filtering to keep rf out of the vehicle electronics .

Today you have to be more diligent than in the past.

Hi Dwayne,

I would like to get one of the SPK20 boards.
My address is:

Randy E. Randall
693 North County Road 575 East
Milan IN. 47031

Thanks,
Randy

Rob,

We've seen more issues like this with the new code. Although we check it very thoroughly, we may have missed something.

We will be starting another round of tests next week to see what we can find.

Dwayne,

I've seen one similar issue on the 1000 ProII. Both the bypass and Ant2 LED come on when Ant2 is selected but it's connected to Ant2 OK. After some use that condition goes away and selecting Ant2 just turn on the Ant2 LED. I can characterize this further if it's of value. I assume the firmware on all the new tuners is either the same or at least based on the same package.

When the tuner power button fails to operate, I reach over and flip the power supply off and back on, saving me having to physically remove the DC power cable from the back of the tuner.

Thanks very much and again thanks for being on the LDG list. It is nice to
have someone from the company there to give us the 'real' answers.

This is what I like about LDG; Dwayne and his company are extremely customer friendly and diligent in researching problems.
I had a recent problem with my Pro 600 and e-mailed LDG directly. It turns out that the problem, even though it resembled one in which I had to send the unit in for repairs, was simply something I missed in reading the manual.

Thanks Dwayne and LDG!

This is an elementary question but please bear with me.

Have an LDG IT-100 connected to my IC-7000.

I use the "tuner" function on the 7000 to tune.

Does the "tune" indicator in the upper left corner of the LCD display have to be illuminated for the tuner to be in the circuit????

From what I see, even after I tune with the IT-100, if the "tune" indicator on the 7000 is off my SWR is high. With the "tune" light on the SWR is low.

5766. Z11pro2 Tune button problem

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2012-11-06 18:24:57 UTC
From: w7spy
Topic: 5766 Message: 5766

Hello... I have a new Z11pro11 tuner; My first auto-tuner. I began with the quick-start portion of the manual, but had to read it all soon. I'm having a problem with the TUNE button, I think. It doesn't seem to make contact uniformly each time pressed. Sometimes it doesn't respond to a brief contact to switch the tuner in and out.

Also, when I tune for SSB using CW tone, PSK31 tone, or whistle, the tuner eventually presents a solid green LED. But when transmitting voice the green LED flickers and often the yellow LED is flickering too. It appears the tuner has forgotten it's tune point and is hunting around while I'm talking. This doesn't seem correct. The green LED also remains solid while transmitting PSK31.

Thanks for your input. Doug W7SPY

Dwayne,

I got a new processor from you today, Nov 6, in the mail for my AT-600Pro. I'm also having all the same problems described in this thread and have tried all the "tricks" mentioned.

I swapped the processor and all the problems are still there. The
only good thing is it does tune all bands and I can safely use my Elecraft KPA500. I get it to the tune state by unplugging and replugging the power cord and, while all the SWR LEDs are flashing, hit the TUNE button once. The flashing stops and the two center PWR LEDs and two center SWR LEDs are now on. This is the auto mode. At this point none of the buttons work. I apply 10W drive on each band and it tunes between 1.0 - 1.5 SWR. It does save the tuned settings. The KPA500 in OPER mode functions properly. However, the AT-600 does not show PWR or SWR levels when I'm transmitting. The four center LEDs just stay constant. As long as I leave the AT-600 powered up it does what its supposed to do. It would be nice to have one where all the buttons/functions work.

Hi Stewart,

Sounds like it's not in the processor.

If the four center LEDs are coming on and staying one, the tuner thinks the tune button is pressed. It may be that you have a home made or bad interface cable. Let us know if you have an interface cable and what happens if you disconnect it.

Date: 2012-11-07 14:28:15 UTC
From: n3pzt
Topic: 5659 Message: 5769

Dwayne,

If you're referring to an optional Icom or Yaesu interface cable plugged into the RADIO jack on the back of the AT-600 I'm not using that. So you're saying it stays hung in the TUNE mode causing none of the buttons to work. The only way to unhang it is to disconnect and reconnect the power cord at which point we're back to the flashing SWR LEDs. I can turn it off with the POWER button when the SWR LEDs are flashing but I can't turn it on again with the POWER button.

For power I'm using a 12V DC 1A regulated wall wart.

Dwayne,

It may be possible the RADIO jack is defective. Using a magnifier I looked inside the jack and see two metal tabs, one on the left and one on the right, which would be the contacts for the tip and ring on the stereo plug from an interface cable. I'm not sure how these tabs should be positioned when no plug is in the jack. Looking closely at the left tab, and maybe the right tab, they may be contacting the bottom inside edge of the sleeve in the jack which would ground either of the tabs. If one or the other is grounded would that cause the 600 to hang in the TUNE mode? Can you test a known good RADIO jack and tell me the continuity of these two tabs and whether they should be open or closed to the sleeve. Maybe the fix would be replacing the RADIO jack but I'm not going to pull it off the board just yet. Thanks.

Stewart,

I doubt it's the jack if you are are not using an interface cable. Look at the interface app note on our support page.

The jack tune signal is electrically tied to the tune switch. So it could be any place from the physical push button on the front panel, through the front panel PC board, through the ribbon cable to the main board, and to the processor.

We've seen a handful over a decade or so get a loose ribbon cable during shipping. I'd try taking the lid off and inspecting the ribbon cable while visually watching the front panel LEDs (no RF will be needed).

If that's not there, it may need to be sent back.

Subject: Re: LDG 1000Pro 2

Hi Doug,

I also have the pro2 and can answer the second part of your question: The green led only illuminates when RF is present hence in CW or SSB, where the RF is intermittent, the led will flash in sympathy whereas on PSK(steady carrier) it will stay on during transmit periods.

The yellow led tells me that you have set, or the default level for the SWR threshold is set to a nominal 1.5-1.8. The swr figure can be pre-set and the manual will help you to sort that.

The” Tune” button issue could be that you are not holding the button in for long enough. The manual calls for a momentary press for one type of operation and a longer (up to three seconds I think) in order to force a different action. Here again the manual will be of help.

The bottom line is that I don’t believe that the tuner has a fault and when you’ve sorted these minor issues, if it works as well for you as it does for me, you will be more than pleased with it.

A final point. From my experience you will not find a better service response than you will receive from LDG. They are first class, going out of their way to help me with a warranty problem I had here in Spain.

Hope this helps .

73,

Wes

Dwayne,

Problem solved. I removed the lid and plugged in the power cord. While powered up I disconnected one end of the ribbon cable from the PC board and reconnected it. All buttons/functions are now working. Possibly this synced the front panel board with the PC board and processor. I guess you could call this a hard reset. Others might want to try this for their hangup/lockup issues.

Looking closely at the left tab, and maybe the right tab, they may be contacting the bottom inside edge of the sleeve in the jack which would ground either of the tabs. If one or the other is grounded would that cause the 600 to hang in the TUNE mode? Can you test a known good RADIO jack and tell me the continuity of these two tabs and whether they should be open or closed to the sleeve. Maybe the fix would be replacing the RADIO jack but I'm not going to pull it off the board just yet. Thanks.

So you're saying it stays hung in the TUNE mode causing none of the buttons to work. The only way to unhang it is to disconnect and reconnect the power cord at which point we're back to the flashing SWR LEDs. I can turn it off with the POWER button when the SWR LEDs are flashing but I can't turn it on again with the POWER button.

> > > > >
> > > > > I swapped the processor and all the problems are still there. The only good thing is it does tune all bands and I can safely use my Elecraft KPA500. I get it to the tune state by unplugging and replugging the power cord and, while all the SWR LEDs are flashing, hit the TUNE button once. The flashing stops and the two center PWR LEDs and two center SWR LEDs are now on. This is the auto mode. At this point none of the buttons work. I apply 10W drive on each band and it tunes between 1.0 - 1.5 SWR. It does save the tuned settings. The KPA500 in OPER mode functions properly. However, the AT-600 does not show PWR or SWR levels when I'm transmitting. The four center LEDs just stay constant. As long as I leave the AT-600 powered up it does what its supposed to do. It would be nice to have one where all the buttons/functions work.

Topic: 5763 Message: 5774

Hi All,

During the contest my Tuner stopped tuning, I had to disconnect from the power,restart tuner, then re-tune into a dummy load. Seems i had tuned to much L on 10 meters.
After going to each band,tuning, all is well. the antenna is a G5RV.

The Power switch problem i'm having happens when i turn off the external power supply. When PS is turned on then pushing power switch on tuner, she lights up however, nothing happens. I have to turn off the power switch on the tuner then turn on again, after the "Double" start, works fine.

Thanks

Herb/KD4Y

Stewart,

Glad that took care of it. The connection to the Tune switch through the ribbon cable is electro-mechanical, so it looks like it may have come loose during shipping.

Dwayne,

Problem solved. I removed the lid and plugged in the power cord. While powered up I disconnected one end of the ribbon cable from the PC board and reconnected it. All buttons/functions are now working. Possibly this synced the front panel board with the PC board and processor. I guess you could call this a hard reset. Others might want to try this for their hangup/lockup issues.

5777. Ldg 600 pro autotuner issue

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2012-11-09 15:57:49 UTC
From: n3pzt
Topic: 5659 Message: 5777

Dwayne,

Almost. Here's the latest. I can toggle the power on/off all day long and all buttons/functions work. However, when the 600 sits overnight, with the power cord connected, here's what happens.

1) If I left it turned off overnight it won't turn on.
2) If I left it turned on overnight it will turn off but won't turn on again.

If I disconnect/reconnect the power cord I'm back to the flashing SWR LEDs. I have to remove the lid and disconnect/reconnect the ribbon cable to get it back to working properly. Tonight I'm going to leave it turned on and see if the buttons/functions work in the morning and not touch the power button. It seems some component goes wacky when it sits overnight.

Topic: 5659 Message: 5778

Has anyone checked the purity of the DC from the external power wall wart to ensure EMI is not the issue.

Was the design of the LDG tuner based on using an external supply seems like the symptoms sound suspiciously emi interference.

Has anyone sent LDG the actual snapshot of what the scope image looks like.

Realizing anything from soup to nuts could be much different than the lab grade power supplies used on the test bench.

the loose ribbon cable should only impact the initial startup a.after receipt from being shipped.
Dwayne what is different in the design from say the kt 100 series Ive seen no issues of turn on is the power more pure after powering from the transceiver

Hi Stewart,

Thanks for the additional information. We're doing an on-going investigation with several units with similar symptoms.

We have several units current on a bench that stays plugged in 24 hours per day and we've been turning them on and off at random times including overnight.

So far, we've not been able to duplicate any problems, but that does not mean they are not there.

As of today (but that could change), we're leaning towards power supply differences. All LDG tuners are designed and tested on exactly the same laboratory style power supplies, so other supplies may produce other results.

I think this will be going on for a while. The first symptoms just started showing up a couple of months ago even through we've been shipping the same products for a couple of years.

This may be a tricky one to solve.

Hi Doug,

The main difference for you is you would not be able to turn your tuner on or off as it's powered from the radio. So you get a hard reset every time you turn the radio on.

The tuners with on/off buttons put the tuner into an on or soft-off mode. In soft-off, almost everything is off and the processor is in sleep mode. The processor only wakes from an interrupt caused by the power button being pressed. It then processes the power on sequence.

We've been doing it like this for many years. We also thought at one time it was a chip run issue that had an interrupt problem, but have since eliminated that direction.

Its an odd problem. Same HW and SW we've used for years, but can't duplicate it on the bench.

5781. Z100 Plus (Raising the SWR lower limit for memory storage?)

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2012-11-09 17:17:28 UTC
From: KHLT
Topic: 5659 Message: 5781

Hi,
Is there anyway way I can increase the lower limit of SWR for frequencies allocated to memory? Just that I have a 1.4:1 (measured on a couple of different meters) on 18m that should be allocated to memory bit it's not..

Is it possible to just lower the setting slightly at the REV TP (is it still TP1/R23 like on the original Z100) would mean that the measured SWR will be lower than actual SWR and more than likely to be stored?

Thanks in advance for any help
Kymmy

5782. Ldg 600 pro autotuner issue

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2012-11-09 17:39:05 UTC
From: n3pzt
Topic: 5659 Message: 5782

Doug,

You gave me an idea. Many AC adapters, such as those for laptops, have a molded ferrite core near the plug to the laptop. Even though my 600 works properly all day long, in the evenings, I'm on my Icom 2200H running up to 65W analog and DStar and I'm on other PCs and laptops. It's possible EMI from one of these devices is getting into the 600 since the cord from the wall wart doesn't have a molded ferrite core. So, I added a snap on ferrite core near the plug to the 600. We'll see if this solves the problem. I've cleared up other problems around the shack with these snap on ferrite cores.

Kymmy,

Yes, that should work. You'll have to play with it to get it exactly where you want it as it will mess up the internal calculation. But R23 should be proportional to the save threshold level.

The risk is that you go too far and the tuner thinks the SWR is lower on other bands. That may effect tuning quality.

Has anyone checked the purity of the DC from the external power wall wart to ensure EMI is not the issue.

Was the design of the LDG tuner based on using an external supply seems like the symptoms sound suspiciously emi interference.

Has anyone sent LDG the actual snapshot of what the scope image looks like.

Realizing anything from soup to nuts could be much different than the lab grade power supplies used on the test bench.

the loose ribbon cable should only impact the initial startup a.after receipt from being shipped.
Dwayne what is different in the design from say the kt 100 series Ive seen no issues of turn on is the power more pure after powering from the transceiver

ThanX Dwayne for the confirmation. I'll first take some initial readings
so I know I can reinstate the current setting if needed. I'm not looking
at drastic changes but to just raise that limit ever so slightly as the
constant need for a retune with a 1.4:1 reading is out of specs and a
bit tedious.

It does make a refreshing change when a company helps it's customers
instead of just repeating a company line of "warranty voided if opened" :D

Checking to see what the current firmware version is on the LDG897 plus and is it marked on the controller chip?

5788. Ldg 600 pro autotuner issue

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2012-11-11 14:49:34 UTC
From: n3pzt
Topic: 5659 Message: 5788

Dwayne,

Well, the problem was the 12VDC 1A wall wart. I hooked up one of my 13.8VDC 3/5A regulated power supplies and all of the problems are gone. I can turn off the 600 and PS in the evening and the next morning turn on the PS and 600 and all buttons/functions work. So, I guess a word to the wise is don't use a wall wart. Lesson learned.

Stewart,

Thanks for the info. Glad it's now working.

Dwayne Kincaid

Stewart WI3JLDG

Hello Stewart,

I was wondering if you could connect back up the wall wart and than unplug the Wall Wart PS, overnight to see if you can get the same good results?

Since the wall wart, was never turned off and was always applying DC power to the LDG tuner, the issue may very well be something else!

I am still having issues with my LDG600, locking up and not responding to any of the push buttons, unless I unplug the DC power cord to the AT600 , and than plug it back up, all returns to normal,
I am using an external Power Supply, not a wall wart.

Are you using the same PS that you transmitter is using? If so, did you
try powering it from a separate PS? It may be RF on the DC lines?

Joe

As I had suggested earlier don't use a wall wart due to emi issues

Here is confirmation by somebody who has substituted a good power supply on the external jack

Doug ve5dcp

Dwayne,

Well, the problem was the 12VDC 1A wall wart. I hooked up one of my 13.8VDC 3/5A regulated power supplies and all of the problems are gone. I can turn off the 600 and PS in the evening and the next morning turn on the PS and 600 and all buttons/functions work. So, I guess a word to the wise is don't use a wall wart. Lesson learned.

I have been experiencing exactly the same lock up issues with my AT-1000ProII and over the past several months I've tried three different power supplies, including a 12vdc wall wart, and two linear transformer-type DC power supplies replete with toroid filtering of the DC power cables. I have come to the same conclusion: use of a wall wart, which always presents 12vdc to the back of the tuner, results in lock up issues.
So, I have abandoned the more convenient wall wart in favor of my Astron RS-35A station power supply, which I shut down after turning off my equipment for the evening. In this way, power is completely removed from the AT-1000ProII, evidently allowing the tuner processor to do a hard reboot the next time it is cycled on.
It seems to me that the tuner on-off button should not allow a "soft" shut down, but instead completely remove all power from the tuner so that wall wart power supplies can be utilized. Clearly, right now that is not the case and should be so noted in the operator's instruction manual that accompanies the product.

Hi Doug,

The gentleman with the problem stated that he was not using a wall wart. He said "I am using an external Power Supply, not a wall wart." I was suggesting that he try a separate power supply if he was using the same one for both the radio and the tuner.

Hello,

Just managed to get hold of a mint AT-11MP via a well known auction site. Thought I'd found an upgrade too but the money has been refunded :-(Does anyone know of any other stockists of the 1.6 CPU upgrade or have one available for sale?

Kind regards.

Martin Fenelon.

Rob,

Yes, I did try leaving the wall wart unplugged overnight and plugging it back in in the morning. The 600 powered up immediately with all the SWR LEDs flashing. None of the buttons/functions worked. I could turn the 600 off with the POWER button but it wouldn't turn on again. Bottom line, the wall wart is bad news. Since I switched to a dedicated 13.8VDC 3/5A transformer PS the 600 works perfectly. When I'm done for the day I turn the 600 off with the POWER button and switch off the PS. In the morning I turn on the PS and hit the POWER button on the 600. All is well.

Interesting. I have both the AT-600PRO and the AT-1000PRO connected to their respective radios via the 'cable' and have never had any problems at all. When I turn on the radio(s), the tuners also powers up and I'm good to go. No wall-warts here at all.

Rob,

Yes, I did try leaving the wall wart unplugged overnight and plugging it back in in the morning. The 600 powered up immediately with all the SWR LEDs flashing. None of the buttons/functions worked. I could turn the 600 off with the POWER button but it wouldn't turn on again. Bottom line, the wall wart is bad news. Since I switched to a dedicated 13.8VDC 3/5A transformer PS the 600 works perfectly. When I'm done for the day I turn the 600 off with the POWER button and switch off the PS. In the morning I turn on the PS and hit the POWER button on the 600. All is well.

From: mcyman
Topic: 5659 Message: 5798

Hi Stewart, Thanks for the info regarding the wall wart. That is rally weird! I guess some wall warts do not work well with the LDG tuners!

A couple of questions come to my mind.

1. I am wondering if any LDG owners are using a WALL Wart without problems, and if so what is the Model number and ratings!

2. I wonder why LDG doesn't supply a Wall Wart. Or recommend one to buy that works without issues.

I do not remember any reference in the owners manual suggesting NOT to use a Wall Wart?

Seems like this is an issue that LDG needs to address, in an effort to minimize customer problems.

Just my opinion.

> Yes, I did try leaving the wall wart unplugged overnight and plugging it back in in the morning. The 600 powered up immediately with all the SWR LEDs flashing. None of the buttons/functions worked. I could turn the 600 off with the POWER button but it wouldn't turn on again. Bottom line, the wall wart is bad news. Since I switched to a dedicated 13.8VDC 3/5A transformer PS the 600 works perfectly. When I'm done for the day I turn the 600 off with the POWER button and switch off the PS. In the morning I turn on the PS and hit the POWER button on the 600. All is well.

I can turn off the 600 and PS in the evening and the next morning turn on the PS and 600 and all buttons/functions work. So, I guess a word to the wise is don't use a wall wart. Lesson learned.

Rob,

1. Tons of LDG customers use LDG products with wall warts. We've never been sent one that didn't work, so there is no way to say why some may not work. The obvious things would be voltage, current, regulation (ripple), and susceptibility to EMI.

2. The web sites for the AT-200ProII, 600ProII and 1000ProII all have recommendations for low cost, wall wart type, power supplies. We have tested these power supplies and found no issues to date.

Dwayne Kincaid

Hello Sigi,

Many thanks for the reply. It was W4RT who returned the money, no more chips available. Oh well, the AT-11MP is still impressive as it is.

Martin.

5806. Z-11 Auto-tune threshold?

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2012-11-25 22:08:08 UTC
From: Charlier26
Topic: 5806 Message: 5806

I read the manual on the Z-11 (not Pro or ProII) and it states that in auto mode, it will retune when the SWR rises over 3:1. Is there a way to lower this threshold?

Thanks

Charlie KB8BWE

Normally when you tune the ATU in USB and any frequency the tranceiver always returns to a frequency 1.40KHz higher than you were originally on.
To solve this change the menu item 47 A1A FREQDISP from ofset to DIR.
This will solve the problem.
I think this is also the case with the yaesu FT-450

Charlie,

There is no way to change the setting on that tuner. You may want to experiment with it some as I recall that it was actually lower than 3:1.

5810. Z11 - Is this diode failure?

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2012-11-29 21:54:48 UTC
From: ferrymanr
Topic: 5810 Message: 5810

My Z11 is failing to tune. Rig is an FT-817. Has worked perfectly for 7 years. ROM version 1.6. I did reseat U1 and U2 but problem remains.
Symptoms:-
1. On start up the first three LEDs flash in sequence.
2. Often it will not register anything on the LEDs after the reboot sequence. Then it will not go into bypass mode. The SWR LEDS do not register anything when I transmit.
3. On 80M when it does run and I fit a 50 ohm dummy load and in bypass mode the rig sees low swr but the Z11 indicates >3.0 On 20M it tries to tune but gets nowhere. On 15 M it seems to tune OK.
Any ideas?
Dick G4BBH

AT100Pro can set the threshold. I have mine set at 1.5:1 and mine locks on at 1.0-1.1 most of the time. Once in awhile I'll get a bad lock where I get higher SWR but still below the threshold. Usually forcing a full retune cycle will cause it to get a good lock.

I own. Z11Pro, AT100Pro and AT200 Pro. They will all tune down to 1.0:1 at times. I have them all set at 1.5:1 threshold and there are times they will stop somewhere between 1.1-1.5:1 but most time they go to 1.0-1.1:1. There are times they cannot find a match but that is with antennas that present worse than 10:1 matches (Think 75M mobile hustler outside 50Khz BW).

I don't know if the PRO2 models are any different but I would be real surprised if they were.

Thanks, I didn't know there was a manual setting. I am thinking of buying one and thats good to know.
SSB locks would be easy but for CW do you find you have to transmit a
carrier for every freq or does it pick up and tune when you start sending morse.

Regards
Paul
I seem to have resent the original email in error

I don't do CW but for SSB it will automatically tune when ever SWR is above set threshold. With voice if there isn't a memory that matches you normally just say AHH until it tunes up. With a tune in memory it normally is tuned by the time you get the first word out. With CW you would probably want to send a carrier for long enough to be sure you had the tune or you risk dropping the first few characters. It usually tunes in less than a second but if there is no memory match it can take 2-3 seconds to find a match.

The one thing to keep in mind when using the auto tune is that if your radio doesn't have a fold back circuit you will be hitting it with high SWR while the tune is happening which can damage it. With most modern radios that have fold back circuits that isn't a issue as they are designed to fold back power if SWR is above 1.5-2.0:1. I've used SWR fold back on FT857, FT950 and TS2000 without an issue but you want to check your radio to be sure it has SWR fold back.

If you go to the LDG web page you can down load the manual. My AT 100Pro allows manual tuning by using the ""F"" key and or ""L"" up or down. I rarely use it as the tuner finds less than 2 to 1 99% of the time.* Dont worry as long as the match is less than 2 TO 1 and the radio puts out full power. *Yes most times the match is less than 1.2 to 1 most often 1 to 1.

From: timelake
Topic: 5820 Message: 5820

I invite AROs who've installed an LDG auto tuner in an MLA2500to share their experiences in detail, along with photos & videos of their project so that those of us who are ready to install one in their MLA2500 can do so effectively and safely.

5821. Installation an LDG Auto-Tuner inside a Dentron MLA-2500

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2012-12-04 19:18:06 UTC
From: timelake
Topic: 5821 Message: 5821

This is a welcome to any ARO who has installed an LDG Auto Tuner in an MLA2500, to sahre their thoughts.

MLA-2500 amplifiers are very limited in space, nevertheless some AROs have installed tuned input boards, triode-contrtol boards and ldg auto-tuners internally in their amplifiers.

I envision that this forum may well serve to guide other MLA-2500 owners to successfully accomplish this with their own amplifiers.

Though the MLA-2500 is obsolete in terms of being of a product of state of the art technology, many of us embrace it's small footprint and have learned to address it's issues.

I hope that those who have installed a LDG auto-tuner inside an MLA-2500 will feel comfortable to share their experiences with us with accurate detailed photos as well as with an instructional video or two.

As an incentive, I'm prepared to contribute my time and skills to help produce an addendum or sorts online, containing your inputs, and have it updated continuously by all of you who have made such an upgrade.

As with all forums, no matter their topic, they serve the community within which some technological void existed.

With respect to the Amateur Radio community, this forum intends to fill the void specific to installing an LDG tuner in the Dentron MLA-2500 amplifier.

In the process of contributing comments and opinions in this forum, please keep in mind that our online behavior may be viewed by both seasoned professionals in electronics as well as by casual amateur radio operators. In either case, abiding by a protocoll of decency, common sense and respect is of primary concern.

NOTE OF URGENCY:
Understandably, since safety concerns are of prime concern with all projects related to HF amplifiers, as their high voltage section can be lethal, it is URGED that what technical guidance is shared here, that this potential for lethality in the MLA-2500 be kept in mind BEFORE attempting any upgrade. Let it known that no one is to be held responsible or liable for any damage or injury as a result of following any amplifier upgrade info contributed here. Suffice to say, let the individual radioamateur be mindful of this caveat of danger as they undertake such upgrades read in this forum and proceed at their own risk. That being said, please take ample precaution to prepare your upgrade procedures to include safety measures, no matter your confidence level or knowledge in electronics.

Thank you in advance for your input and I welcome your contributions to this forum!
(My sincere thanks to all concerned with availing us this forum to enjoy and learn from!)

Terry

Sound like you have a great multiband antenna

Simple 1:1 is a perfect match and the tuner goes to bypass right away(no adjustments needed)

You have forgotten some basic principles it sounds like the only band it tunes is 20m.

Did the ham radio trainers doing ham radio classes forget to mention what 1:1 means?.

Different antennas are lots of fun

Cheers

Merry Christmas

Terry:

Why would you need a matching device if the SWR in very close to 1:1?
The AT-200 is probably smart enough to default to bypass.

Thanks guys, it looks a good bet for SSB but if it needs a carrier to initially remember the freq it means I will have to drop an AM carrier on every CW freq I use..... not sure if it's worth the trouble. At present I use a mobile ATU, MFJ-973 which works fine and only have to tune on each band but it will not touch 17M,so I wanted something stronger and fast. How do you CW ops fare ??

Why would you have to drop to AM on a CW freq? Can't you just send a
carrier with your key?

5828. LDG AT- 1000

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2012-12-15 17:20:24 UTC
From: cadiscase
Topic: 5828 Message: 5828

Is anyone using the AT-1000 with an SB-220 or an HL-2200 amp ?

Something that has an input of 2kw with an output about 1200 watts PEP ?

Thanks

5829. AT 1000 LDG tuner

Has or Is anyone using the AT - 1000 auto tuner with an SB 220 or an HL 2200 amp ?

I want to know if the tuner can handle that amount of power with I assume is about 1200 PEP .

Thanks

I use a paddle, even slowed down the dashes aren't very long duration.
maybe not long enough for it to lock on. Think I'll just get an old hand key and use that.
Thanks

5832. LDG AT1000 First generation

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2012-12-17 17:54:24 UTC
From: alxnndr
Topic: 5832 Message: 5832

Hi,

Apologies if this is in the wrong place, I have an LDG AT 1000 that appears to have stopped tuning. I see the needle bounces, but I'm still reading 3:1 on 40 and when I key up even after a reset I do not hear any relays clicking. I have tried connecting directly to the tuner and eliminating the Ameritron 811 from the mix, but I am getting the same lack of response. I hav a smaller 100 Pro II that tunes quite well with the same antenna and radio, but the AT 1000 does not seem to be doing anything.

My second problem is with LDG in particular. Has anyone tried calling them recently? I have left voice mail and now email and I am getting no response. If anyone from LDG is here, I would appreciate a word back, and more importantly if anyone here on the list has any idea what might have happened to my tuner and how to fix or troubleshoot it, I think I would appreciate that even more.

Many thanks,

George

Hi George,

I think we got the technical parts taken cared of today.

The response time is much slower as we get closer toward the holidays. More people here are on vacation and it didn't help that I broke my foot last week by dropping a 50 pound power supply on it.

I would guess we'll not see an improvement in phone response times until after the new year.

5841. AT-100Pro on 160 meters

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2012-12-20 14:42:22 UTC
From: cadiscase
Topic: 5841 Message: 5841

I am using the AT-100 Pro on a dipole ant.
The unit works good on all bands but 160 meters.
When I apply power [FT-101EE 50 watts] to the tuner on 160 it seeks for a match and finds it at less than 1.5 SWR.
I have the threshhold at 2.0.
The next time I apply power to the tuner it retunes again.
It should not retune since it found a match and does not retune on other bands, but only on 160 meters.
I do have the tuner grounded.

Any fixes?
I think I have the latest version 1.3 of software.

Thanks

5844. Re: Ldg 600 pro autotuner issue

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2012-12-23 09:04:46 UTC
From: Dana
Topic: 5659 Message: 5844

This week my AT-600Pro has begun locking up when the TX (K3) is in Tune mode (no interface). It may make an attempt to tune but it quickly locks consistently. It usually (but not always) displays 3 leds on the top bar and all leds on the bottom bar. I can reset by unplugging the power, but it locks the next time I try. I don't know if this is the same problem or something new.

Thanks for your assistance

5846. Really Confusing Z11 Pro 2 Behaviour

From: pjayuk
Topic: 5846 Message: 5846

Hi Guys from the UK

I really hope someone can help me understand whats going on with my Z11 Pro 2 as I am currently thinking of selling it as its driving me mad!

I have it connected to my FT-897D (no ACC connection)with an inline SWR bridge which is connected directly to the radio. So in order it goes Radio --> SWR Bridge --> Z11 --> Antenna. My antenna is a multiband off centre fed dipole up about 20 feet at the end of my garden, its connected to a long feeder of around 180 feet of RG213/U coax which enters the shack. According to the manufacturer the antenna should be usable on 20,17, 15, 12, 10 and 6M. According my readings the antenna present a swr of 1.5 on 20 with the rest of its range at around 2.5 - 3.5. I want to use the Z11 to bring the SWR down as low as possible, which the internal ATU in the FT-450D does with ease across all the bands that I use this antenna on.

The Z11 has no problem getting a perfect 1:1 match on 20M and 10M. On the 15M band it chatters away for a good few seconds before displaying the "no match found" LED sequence. The same applies to 12 and 6M making these bands unusable with the Z11 Pro2 inline (as I also cant get it to bypass properly either!).

Watching the SWR meter during the tuning process I can see that the SWR goes well into the red zone on the meter before the tuner gives up without a match. This doesnt seem right to me especially given the SWR on 15M is only around 3 to begin with I would expect any tuner to be able to easily match as indeed the internal one in my FT450D does without any issues.

So any help here would be hugely appreciated I would love to know if I am using this thing incorrectly or perhaps if it might be faulty?

Thanks and 73

Paul 2E0PJY

Just for clarification, I am using the LDG tuner with my FT897 but also have an FT450D in the shack which I have been using for my comparisons. it wasn't too clear on the original post.

73 DE Paul.

Are you running a choke on the coax. The kind of problem you describe
sounds like RF on the Coax messing with the LDG.

Hi Leonard

Well I am amazed thanks so much for your advice. I removed the 8 turns of coax at the foot of the antenna and the tuner now tunes perfectly on all bands (apart from 50Mhz but I am not too worried about that). I guess though this does raise a couple of questions...

1 Whats the theory behind why the choke would cause the tuner to behave in this way?

2 How did the internal ATU in my FT450D which has a much poorer tuning range manage to tune the antenna when the Z11 Pro 2 wouldnt?

All in all I am very happy with the unit now and wont be selling it but would be interesting in learning why the above are the case!

73 and happy new year

Answer to Q - 1: I'll leave it to the experts, but you have an unbalanced (coaxial cable) line feeding an unbalanced windom, so it seems a crap shoot to me that anything works. You MUST have RF on the outside of the coax. If the transmitter end is at a "hot" wavelength away from the feed point of the antenna you could have mucho RF getting inside the Z-11. But, as my pappy told me, when I was knee high to a grasshopper, sitting on his knee whilst he was making contacts on AM (back in the 40's and 50's before SSB), "If it works, don't screw with it."

Answer to Question II - My guess, based on practical experience, is that the ATU in your FT-450 was completely shielded from any RF floating around the outside of the coax, and therefore "saw" what the coax presented. With the extra (short) coax between the Rig and the 897 and a DC connection and "tune" wires connected externally, there were several paths for RF to get into the innards of the Z-11. You might verify this by trying to run your 897 @ <5 watts, and see if you'd get a match. There would be about 13 dB different in circulating currents on the outside of the coax, so the Z-11 might work fine at QRP levels. That might "prove" that the problem was/is due to antenna currents existing on the outside of the coax.

But, since you've figured out a way to accomplish your goal, you might just take the advice of my pappy and run with it.

An interesting problem - and set of replies.

I had problems with my Z-11 Pro that seem quite similar - and my antenna is one of M0CVO's off-centre fed dipoles. My experience (shared on here some time ago) was that the tuner worked fine, but once the power level was raised (sometimes not very far!) it appeared to "lose" its setting and didn't regain it.

I fitted a good RF earth system, and tried all manner of RF chokes and "isolators" between the antenna and the radio setup. I replaced the entire feedline with better coax (not that the original was either particularly bad or very old) and finally managed to get the thing to behave - I recorded this achievement here on the forum, and felt pretty pleased with myself. Unfortunately, when I went to repeat my tests the next day, the problem was back.

I fought on with the setup for another couple of days, then decided I was just wasting my "hobby time" - so I put the Z-11 in the cupboard and got my old MFJ 969 out. (I didn't fancy coming back to the forum on the subject - not because there was any adverse comment or criticism, but because I thought I'd tried all the likely advice, so maybe I'd bought a duff unit from eBay).

Recently, I decided to have another go, going right back to basics. Spent a few hours testing, disconnecting bits of equipment, swapping things round and so-on - and suddenly the problem was gone. All I'd done was to refit a cable in its original position - I can only conclude that the finish on the PL259 was somehow imperfect, giving the impression that it was fully tight but not providing a sound connection once the power was increased.

I'm not sure where that leaves me, but I suspect the tuners are really rather sensitive to a bit of stray RF, and that the RF came from the poor plug connection acting like a "rusty bolt". I was not aware of (and certainly could not detect any) stray RF in the shack, but I cannot see an alternative conclusion. My tuner has behaved perfectly since then (only about a week, I admit) - tunes my HP-40 on all bands from 3.5 to 50MHz.

My antenna, like yours, is not high - only about 20 feet up at the feedpoint. I probably have 60 to 70 feed of feeder in total. The only concession to trying to limit RF on the coax is 12 turns of coax (Mini-8) on a Fair-rite FT240-43 toroid where the coax enters the shack.

Not sure whether any of this is of benefit to you now you've got things working (and I do endorse the view that "if it ain't broke, don't fix it"), but I thought it was worth sharing the learning points.

Thoughts welcome.

All the best (and Happy New Year to all!)

Tony M (G4TRY)

Hi Tony

Very interesting and similar problem to mine. I too had though about getting my manual Palstar tuner out but the LDG seems to be behaving so far. What I am confused about is the internal ATU in my FT450D has no problem tuning all the frequencies that the M0CVO HW20 claim to be usable on however the 450D is not the radio I use most often I prefer my 897D with the LDG Z11 Pro2. I am surprised that the rather limited range internal ATU has no problem and the LDG does.

The Palstar however would tune a pair of the wifes panties if only I could string them up on the mast (not sure if I would need a balun)...

I am going to take your advice and disconnect everything and reconnect to look for a dodgy connector although since an earlier post I removed a coax choke and things are much better!

From: na5ss
Topic: 5846 Message: 5854

I had exactly the same problem with my Z-11Pro II that would not tune on 15 meters. I fixed the problem by adding a coaxial balun inside of the shack. I uploaded some pictures in the photos section.

Thanks for the posts to resolve the problem.

> Very interesting and similar problem to mine. I too had though about getting my manual Palstar tuner out but the LDG seems to be behaving so far. What I am confused about is the internal ATU in my FT450D has no problem tuning all the frequencies that the M0CVO HW20 claim to be usable on however the 450D is not the radio I use most often I prefer my 897D with the LDG Z11 Pro2. I am surprised that the rather limited range internal ATU has no problem and the LDG does.

My experience (shared on here some time ago) was that the tuner worked fine, but once the power level was raised (sometimes not very far!) it appeared to "lose" its setting and didn't regain it.
> >
> > I fitted a good RF earth system, and tried all manner of RF chokes and "isolators"

between the antenna and the radio setup. I replaced the entire feedline with better coax (not that the original was either particularly bad or very old) and finally managed to get the thing to behave - I recorded this achievement here on the forum, and felt pretty pleased with myself. Unfortunately, when I went to repeat my tests the next day, the problem was back.

Topic: 5855 Message: 5855

Hi,
Thought I would try and tune 5mHz and the it 100 would not tune up the antenna......there are lots of questions here just don't know which ones to ask. Any ideas? Does the 7200 need a mod to work this band?
A good website with information on 5Mhz operation with the 7200?

Thanks,
Chuck

From: caymann
Topic: 5856 Message: 5856

I am trying to use this tuner in Auto or manual mode and i am not able to get a low SWR

I have a Flexradio 3000 which has a TUNE button and sends 10W out.
I have set the tuner into AUTO mode and ANT1 has antenna connected

I can easily tune the antenna with the built in tuner on my Flex 3000 radio. However i want to use a 500W amplifier and hence the need for the AT-1000Pro tuner.

The tuner initiates the process and eventually gives up....i think.
The LEDs (all of them) blinks three times when it is done.
I read a high SWR on the radio and close of 5W of reflected power when i am sending 10W out to tune.

I set the AT-1000Pro to look for a 1.2 SWR

Any way to get this tuner going?

best regards
jim

5857. KT-100 with TS-480SAT

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2012-12-31 03:46:40 UTC
From: Avery
Topic: 5857 Message: 5857

Please help with advice on using a KT-100 with a TS-480SAT. Both were purchased recently. I think I have followed the instructions correctly. The KT-100 is connected to ANT 1 jack, and menu #27 is set to At1. But when I press the AT button, nothing happens. When I hold the AT button, after a second the display momentarily flashes "R < AT > T", and the red LED on the KT-100 flashes four times, but no tuning took place. I tried reducing the power to 10W, then transmitting CW while holding the AT button, and the KT-100 does tune just fine (same as when I press the front panel tune button, the red LED comes on while I hear the relays chatter, the red goes out and the green LED comes on). With my antenna, the SWR goes from about 3:1 to about 1.1:1 according to the TS-480SAT display. But, the "AT" area of the TS-480SAT display remains blank, unlike when I use the internal tuner (i.e., I get the "R < AT > T" icon). I got the KT-100 to use as a remote tuner, so I have cut the supplied control/power cable to splice in longer wires, and I have double and triple-checked the wiring for correctness. My question is, what else can I do to get this KT-100 to work "transparently" (i.e., just like the internal tuner)? Or is it supposed to work this way?

Thanks & 73,
Avery, WB4RTP
Tucson, Arizona

Hi, Jim,

I have a FT-990 in front of my AT01000Pro that I can reduce power down
to 10 W. I attempted to tune non resonant antennas with over 5:1 swr.
The tuner did take a few seconds to tune, but it got down to nearly 1:1.
I tried it on a number of combinations of antennas and frequencies and
it worked every time so I don't think it's a design problem. With the
AT-1000 in standby, can you tune with the Flex?

I found out the hard way that when the tuner is powered off, Antenna 2
is selected in passthru mode.

I haven't tried loading a wet string yet, however. ;)

Jim.

The default of the tuner is ANT 2.
Try connecting your antenna to ANT2.

I just purchased the new Yaesu HF rig. A fellow at HRO suggested I get a separate tuner for the Yaesu even though it has one built-in.

I know LDG makes great products, but not sure if this is necessary or would be an improvement and wanted to get some input.

I do currently have an Icom 7000 and use the LDG 100 tuner specific for the Icom and has been a great setup with my Budistick antenna (I'm in an apartment situation with a balcony).

Thank you.

Lance K7LER

Hi All,

I am trying to tune my new diamond HF80CL antenna to my Yaesu 857 for mobile use on 3.944 lsb... So far it will not tune to get good swr. I am using the LDG z100 plus. It only will go thru the cycle if I talk while keying up the mic. Otherwise it blinks 5 times and no cycle just keying up the mic.

If I talk it will cycle but it will not tune. I tried moving the top element up and down is small intervals but it still wont tune.

Any ideas on what I am doing wrong

Hi,

We're going to need to get a little bit of info first.

You know bypass is just another L/C combination right? By pressing one of the L/C up buttons to switch in some capacitance or inductance it should take the tuner out of bypass?

Have you tried setting the tuner in fully automatic mode and sending a carrier to see if it tunes?

What type of antenna are you using with the tuner, what is your feedline to the antenna, and what radio are you using?

Cheers,
Josh

From: cadiscase
Topic: 5868 Message: 5868

When I run my LDG AT-1000 ProII through a full tuning cycle, does it try ALL combinations of C and L ?

IN other words, is there any advantage to increasing C or L and then try a tuning cycle, - will this selection try more varied combinations than a full cycle.

Thanks

5870. Performance on 6 meters

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2013-01-15 18:43:55 UTC
From: ae6rhxx
Topic: 5870 Message: 5870

I recently bought both an LDG 600 Pro tuner, and a Hex Beam Antenna from K4KIO.

after adding a 6 meter element to the Hexbeam, I was having some difficulty getting the LDG tuner to work properly on 6 meters. I had left another tuner in series with the tuner (an MFJ 962D) so I could use either tuner independently. this worked fine on 15 - 80 meters, but something started happening on 6.

It occurred to me that perhaps on 6 meters there was too much going on and there might be some ground loop or other interactions that only show up on 6, so next I removed the MFJ tuner.

as soon as I did that, the VSWR on the 6 meter Hexbeam dropped down to 1.1:1 from 50.0 to 50.8 MHz, and peaked at a ~3:1 around 53 MHz.

I just joined this group and did notice a lot of 6 meter issues. I'm still not saying the tuner will work on 6 meters as I didn't check it where the antenna is ~3:1, but that's next.

Leonard:

This seems to be the case. This comment caused me to look up internal pictures of the MFJ962D to see how it's wired. (I believe the picture below is correct.)

http://kitty.rimtai.com/chtr/products/MFJ/images/MFJ-962D-2.jpg

When you look at the way the connections are run between the SO-239s and the coax selector switch it's pretty clear there could be a problem on 50MHz, even when in bypass. Individual units may even be worse.

Mike, I'm trying to fit a 2.1mm ID, 5.5mm OD plug into the jack, and my plug is apparently too BIG, not too small.

Found the answer on their website. You were correct. 2.5mm x 5.5mm.
Guess it was the center pin of the jack being too big that wasn't letting me plug it in.

5878. Re: Performance on 6 meters

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2013-01-18 02:33:34 UTC
From: ae6rhxx
Topic: 5870 Message: 5878

Thanks for all the feedback. I have taken the MFJ tuner out of the setup & now the LDG tuner works somewhat when I try to tune the Hexbeam above 52 MHz, where the match starts to approach 3:1.

But the best the LDG seems to be able to tune is ~ 1.8:1.

When I check on 50.125 or thereabouts, the VSWR with the tuner off is very low; ~ 1.2:1 max. so I really don't need the LDG tuner at all; but, after reviewing your comments on the MFJ tuner not designed to work at 50 MHz, it occurs to me that I also have an Ameritron 811 amplifier in the circuit, and even though it's off, and in the bypass mode, it's still could be contributing to a similar problem? maybe I need to re layout the station so that the amplifier is only in the link from 10 - 80 meters?

What I'm really curious about is have any of you used an LDG tuner on 6 meters, and was it capable of bringing the VSWR down to < 1.3:1?

5879. Yaesu FT-950 with LDG AT-600 PRO or PRO II ?

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2013-01-18 05:57:31 UTC
From: bob.k6rwm
Topic: 5879 Message: 5879

Brand new to the group. I am considering buying the AT-600 PRO II for use with my FT-950. I am using a full size G5RV at 40 feet, and the auto tuner in the Yaesu just will not hack it. Right now I am using a Palstar AT1500CV, which seems to work okay, but I really want to get an auto tuner. Jumping from band to band on PSK or whatever takes some time with the manual tuner. I may be able to fine tune the Palstar to a lower SWR than with the LDG, but I feel the difference would be minimal. What's a few watts between friends?

All that to say, or ask, does anyone have any experience with this combination? I would be interested in hearing your input, good or bad before I run out an spend money.

LDG is a nice tuner. I use a AT200pro. Keep in mind that the AT600 doesn't interface directly to the radio. By this I mean that the tune button on the tuner will not make the radio tune (there is away but you would need a special cable to the linear jack). It really is not a issue though. LDG tuners will start tuning as soon as they see RF and the fold back in the radio will protect the finals until a tune is reached; however, if you believe you need to turn the power down while tuning, you will need to change modes and set power manually. I have the power turned down on AM and just switch to AM when I want to send a carrier tune.

yes and yes.I have a Z11 Pro and a Z11 Pro II,both work/tune 6m
both a 40m loop or a 31' vert.
The tuning range is less on 6m than on hf.
Have you tried to manually get the swr down after an auto tune?
(C up C down, L up L down with a carrier applied) A lot of times I can get a little better swr doing that

thanks Scott,

I have tried manually tuning and I still only get ~ 2:1 best;

so now I'm going to disconnect the 811 amplifier, which also is not specked above 30 MHz, and see what happens?

When I measure the VSWR on my K3 meter at 50.125 MHz, I get very low readings; 1.2:1 max and the signal is still going thru the amplifier, but it may be the combination of tuner AND amplifier that's getting involved.

I have an AT-1000 proII and a Kenwood transceiver. I know that the interface does not work with Kenwoods. I also have an Arduino communicating with the Kenwood.

If that interface provides a signal to begin autotune and maintains that signal until tuning is complete I could use it. I would have the Arduino change the mode on the Kenwood to CW, disable linear keying, transmit until the tuning cycle ends and then change the mode back to it's former setting. That would be very cool.

Glad you got one. They are good tuners.

Actually I wasn't saying that you needed to watch it. The fold back
circuits will do that fine IMO. I was just pointing out if using the
fold back bother you then you need to realize that there is a work around.

I would have the Arduino change the mode on the Kenwood to CW, disable linear keying, transmit until the tuning cycle ends and then change the mode back to it's former setting. That would be very cool.

Karsten,

I have a FT-857D. The setting for the radio should be the same.

Install the cable between the radio and tuner.

Press the [Function Button] go to MENU MODE 020 CAT/LIN/TUN

Rotate the VFO knob to TUN.

That should be it.

73,

Mike, NA5SS

Hi Dwayne,
I am very curious about some software to measure the SWR and more how to determine its sign (L or C)
Is there a way to have simple examples of this somewhere?
Maybe that's the message is vy old, but I do not find anymore the W4RT file about the memory structure.

Thanks , 73 de Augusto HB9TZA / I2JJR

(Still using ok your Z11 un-pro , ex kit , with the upgraded chip)

Hi , Dwayne and All,
sorry , I intended the code used to measure SWR , the Resistive value,
(real part) and if Inductive or Capacitive reactance (the imaginary, j ,
part) is present.
Some example available somewhere?
Thanks!

5898. AT-1000Proll on 160

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2013-01-29 17:13:24 UTC
From: cadiscase
Topic: 5898 Message: 5898

I have the AT-1000Proll and want to use it for 160 meters.

Unfortunitly, I do not have room for a 160 meter dipole.
I have a dipole where one leg is approx 70 ft and the other leg is approx 55 ft. I am feeding it with 450 ohm ladder line.
I put an extra 20 feet of ladder line on and tried to get a match.
I did this, cutting off about 3 feet each time , and was never able to get a match.

Assuming a person can not get a full 160 meter dipole, what is working for any of you to get on 160 meters ?
What is the length of your dipole legs and what is the length of your ladder line - what combination is working for you ?

I realize what works in one place will not necessarily work in another.

Thanks for any suggestions or relating what is working for you.

Have you tried hooking both of the wires of the ladder line together,
and feeding it as a topvertical with top loading? The other idea would
be to add loading coils in the center of each of the dipole elements,
but you'd have to have a way of shorting them out for other bands.

Feeding a 1/4 wave antenna in or near the center is very tricky because
of the very low impedance there, and the rapid change in impedance as
frequency changes.

I've loaded a 40 meter dipole fed with 450 ohm window line on 80 meters,
but it was very very tricky, and I had to retune every 20 KHz or so.
And, picking the right length of feedline was a crap shoot, seemed to
depend on whether the line had any water on it.

5901. Z-11 Pro II Troubleshooting Help Sought

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2013-01-29 08:04:13 UTC
From: sohosources
Topic: 5901 Message: 5901

Hi, gang,

I'm looking for ideas on fixing my Z-11 Pro II, which has just become "goofy" after working perfectly for 1.5 years.

It's remotely mounted in my attic, where it feeds a 40-meter horizontal loop via a 20-foot length of open-wire line. The tuner, accessible through the attic hatch in my upstairs hallway, is itself fed with a 50-foot length of RG-6 coax.

I run 1-10 W (QRP only) on 160 through 6 and, as mentioned, the PRO II has been chugging away for 1.5 years without incident.

I hadn't been on the air for a few months, so I was interested in torturing myself in the 160 contest the other day, when I noticed the the tuner would not provide a match (on any band).

The tuner is powered by a pair of lantern batteries. I initially thought that the batteries had died, but they are putting out 10.1 V, which is way above the 6-V minimum.

I brought the tuner into my shack, powered it with the same lantern batteries, and noticed that it responds to all pushbutton commands, lighting the appropriate LED sequences, etc, but it will not tune.

I opened the case and looked for burned/damaged parts, and the only thing I can see is a very slight "burn residue" on the input/SWR detector toroid (which could possibly have been caused by a soldering iron during manufacture). It's not a jagged burn mark, just a hint of melted enamel or whatever).

I haven't looked at the schematic, but I tested two pairs of diodes with my DVM (one large, black pair near the toroid, the other small-signal types an inch or so away). The big diodes measured several megohms one way and completely open the other, while the smaller diodes had non-open readings that were different from each other. Again, I don't know schematically what might be connected to those diodes.

I'm assuming that, because the tuner seems to respond to button commands, that the problem is in the input / SWR detector part of the circuit.

As I don't have any practical experience with these, I'm hoping someone on the list might be able to offer a suggestion or two.

Also, if I can't fix it, does anyone know what these things typically cost to repair at LDG? The web site is rather vague! :)

Thanks!

Does anyone know the frequency size of the memory segments on the various bands for the AT-1000ProII?

The manual says - "Memory frequency step sizes vary with the selected band" but doesn't get specific.

The more segments I can pre-tune, the faster the switching when operating.

I built a GM0ONX INVERTED L ANTENNA FOR 160, 80 AND 40.

It works fairly well and got me on 160m which I was never able to do before. It is amazingly broad banded. It works and I have made QSOs with it up to 1500 miles away. It works for me and got me on the band.

I am sure there are other options you can consider.

Good luck!!!

I am directing this to Dwayne in particular. My AT-1000PRO stopped tuning and the meter does not read any RF whereas an external meter shows RF output. I took the version 2.0 chip out of the unit and replaced it with the 1.2 chip and the meter now functions but the tuner will not perform a complete tune. I am able to manually tune the tuner however. Is there any way to obtain a version 2 chip to replace the dead one I have?

John,

Each tuner is slightly different. On 80M the spacing is about 20 KHz on 10M it's about 100 KHz.

Kirk,

That is an odd issue. You can use 1N34A diodes. Send some RF through the tuner (while in bypass) and measure the voltage at the F and R test points. You should see a volt or so at the F point with 10 watts and no volts on the R point when the SWR is good.

Just about all repairs are different, so it's hard to tell what a repair is going to cost before we look at it.

Dwayne,

Thanks for your input.

I will run a voltage test or two and get back to you...

On repair costs: I obviously won't hold you to it. but perhaps you can provide historical repair cost ranges?

A new tuner is about $160, so if it's close to that, it's probably better just to buy another unit. If it's $20, there's no need to troubleshoot on my own :)

You get the idea :) Can you provide any further repair cost data on the Z-11 Pro II?

Thanks for your help. I appreciate it,

Dwayne and the gang:

I have compiled some test data. I'm posting it on the list because it may be helpful to others. If the list owner prefers that I not continue this, please let me know. :)

Dummy Load = 52 ohms.

Power = two lantern batteries in series (1.5 years old, not putting out full voltage).
No load = 10.1 V
While tuning = 8.7 V

80 m on Dummy in BYPASS MODE:
10 W - FWD TP = 1.31 V dc; REV TP = -8 mV
1 W - FWD TP = 0.369 V dc; REV TP = -20 mV
SWR shows 1:1

20 m on Dummy in BYPASS MODE:
10 W - FWD TP = 1.34 V dc; REV TP = -75 mV
1 W - FWD TP = 0.38 V dc; REV TP = -33 mV
SWR shows 1:1

6 m on Dummy in BYPASS MODE:
10 W - FWD TP = 1.175 V dc; REV TP = +63 mV
SWR shows as 1.3:1

6 m on Dummy after AUTOTUNE:
LEDs 1 and 4 stay lit, controls unresponsive, power cycle required to reset.
(Happened on other bands, too.)

Random wire on 20 after AUTOTUNE:
match, all functions normal

Random wire on 6 after AUTOTUNE:
No match found, LEDs 3 and 4 stay lit, power cycle required to reset.

When trying to match the random wire, the unit will autotune whether in AUTO or BYPASS modes (the LEDs blink the proper ack sequence when the modes are changed, but the unit autotunes no matter what, not finding a match :)

I hope this provides additional troubleshooting info!

Ideas, anyone?

As always, thanks for your help,

10.1V may mean one or both batteries are bad. I have seen batteries that TOK with a voltmeter, but do not work under load. That's why even my cheap Radio Shack battery tester puts a small load on the battery while under test. When the relays start clicking the voltage may be dropping. You may not see this momentary drop on a voltmeter.

Try powering it from a known good source. It sounds like your lantern batteries may be toast.

As I suspected, your doing your test with bad batteries. Your almost
dead batteries may supply voltage, but not be able to supply enough current.

Hi Kirk

Mounting it in the atiic is a different place for a tuner

Wondering if the thermal conditions in the attic have destroyed the electronics as the attic temps can be 110-145 F in the summer (northern latitude eg 50 degree N) and like close to outside ambient in the winter all depending on the amount of ventilation used to lower the heat in the summer.and if its thermally controlled or a wind driven whirly bird depending on the wind conditions

I would ask what part of the country you are in to ascertain the type of possiblle damage done.

The location of the gear(in the attic) likely has a large bearing in why it has failed.

All it take is to hang a thermometer in the attic for a few hours you may be surprised what you have subjected it too in both summer and winter

Did you check the environment recommendations in the manual.

as dwayne has stated really hard to give cost sight unseen.

Generally most gear begins doing strange this at 80% of nominal voltage that means 9volt on a 12 v source.

The nominal design spec are usually +/- 10 %.

Your data looks like time to get rid of those batteries.

Even the no load static looks low

Subject: Re: [LDG-auto-tuners] Re: Z-11 Pro II Troubleshooting Help Sought

Dwayne and the gang:

I have compiled some test data. I'm posting it on the list because it may be helpful to others. If the list owner prefers that I not continue this, please let me know. :)

Dummy Load = 52 ohms.

Power = two lantern batteries in series (1.5 years old, not putting out full voltage).
No load = 10.1 V
While tuning = 8.7 V

80 m on Dummy in BYPASS MODE:
10 W - FWD TP = 1.31 V dc; REV TP = -8 mV
1 W - FWD TP = 0.369 V dc; REV TP = -20 mV
SWR shows 1:1

20 m on Dummy in BYPASS MODE:
10 W - FWD TP = 1.34 V dc; REV TP = -75 mV
1 W - FWD TP = 0.38 V dc; REV TP = -33 mV
SWR shows 1:1

6 m on Dummy in BYPASS MODE:
10 W - FWD TP = 1.175 V dc; REV TP = +63 mV
SWR shows as 1.3:1

6 m on Dummy after AUTOTUNE:
LEDs 1 and 4 stay lit, controls unresponsive, power cycle required to reset.
(Happened on other bands, too.)

Random wire on 20 after AUTOTUNE:
match, all functions normal

Random wire on 6 after AUTOTUNE:
No match found, LEDs 3 and 4 stay lit, power cycle required to reset.

When trying to match the random wire, the unit will autotune whether in AUTO or BYPASS modes (the LEDs blink the proper ack sequence when the modes are changed, but the unit autotunes no matter what, not finding a match :)

I hope this provides additional troubleshooting info!

Ideas, anyone?

As always, thanks for your help,

Hi Kirk

Mounting it in the atiic is a different place for a tuner

Wondering if the thermal conditions in the attic have destroyed the electronic as the attic temps can be 110-145 F in the summer (northern latitude eg 50 degree N) and like close to outside ambient in the winter all depending on the amount of ventilation used to lower the heat in the summer.and if its thermally controled or a wind driven whirly bird depending on the wind conditions

I would ask what part of the country you are in to ascertain the type of possiblle damage done.

The location of the gear(in the attic) likely has a large bearing in why it has failed.

All it take is to hang a thermometer in the attic for a few hours you may be surprised what you have subjected it too in both summer and winter

Did you check the environment recommendations in the manual.

Subject: [LDG-auto-tuners] Re: Z-11 Pro II Troubleshooting Help Sought

Kirk,

That is an odd issue. You can use 1N34A diodes. Send some RF through the tuner (while in bypass) and measure the voltage at the F and R test points. You should see a volt or so at the F point with 10 watts and no volts on the R point when the SWR is good.

Just about all repairs are different, so it's hard to tell what a repair is going to cost before we look at it.

5914. Ldg 600 pro autotuner issue

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2013-01-30 16:24:40 UTC
From: n3pzt
Topic: 5659 Message: 5914

Dwayne,

I had the same issue as Vince several months ago and you sent me a replacement microprocessor. That didn't fix the problem. I was using a 3/5A regulated PS and switched to a 20A regulated PS with a 10A fuse. That fixed the problem.

However, now the 600 is blowing fuses in the PS. Yesterday I got a new 3/5A regulated PS with a 1.5A fuse and the 600 blew that fuse twice. I switched back to the 20A regulated PS with a 10A fuse and the 600 blew that one also. There's no shorts in the DC power cable to the 600. It seems the 600 is drawing more than 10A which would indicate maybe a shorted component, such a diode, in the 600. As a test I attached a 1157 brake light bulb to the new 3/5A PS, after replacing the fuse, which draws about 2.5A , and it ran fine all day. Any suggestions.

Hi there...

I have an AT200ProII that is doing the same thing as Tom's tuner... LEDs work to check functions, but the LEDs cannot seem to be restored to working during tuning... I have done the sequence to turn ON the LED indications and that doesnt seem to work. Resets dont do anything.

Thanks.

I will try new batteries later today.

I was originally going to replace them as a matter of course, but because the tuner is spec'd down to 6 V, I figured 10.1 V would be okay... Geez!

If this is my "fix," I'm gonna be a bit embarrassed !!! :)

--Kirk, NT0Z

P.S. In the interim I'm using my old SGC autocoupler (circa 2000) which, for the past few years, often requires 10 W to initiate a tune cycle. My previous radio only went to 5...but my present KX3 does 10+ on all bands, which makes the SGC usable again. Because the SGC is powered from an ac mains-connected power supply, on 160, even at 5 W, I trip the GFCI outlet in my office/shack, which plunges me into darkness on the first dit! My PCs, on UPSs, don't crash, but the experience is unsettling... The battery-powered Z11 doesn't do this. I will be happy to get back to the Z11, which tunes easily at 1 W...

I wish LDG made an autocoupler... I prefer to place the tuner at the feed point...

Dwayne,

Solved. I swapped the microprocessor and unplugged/replugged the ribbon cable and all is well. No blown fuse on the 20A PS. I'm down to my last fuse for the 3/5A PS so I'll try that one again when I get more 1.5A 5x20mm spare fuses.

5918. Re: Fwd: [LDG-auto-tuners] implementation of SWR measure and sign, by Firmware

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2013-01-31 03:05:23 UTC
From: Dwayne
Topic: 5896 Message: 5918

Hello Augusto,

We don't measure the Resistive value or Inductive or Capacitive reactance. All we measure is the forward and reverse RF power. The SWR is calculated from that.

You may want to review the original AT-11 article from 1995 that describes how the tuning algorithm works. It's available at our web site on this page: http://www.ldgelectronics.com/c/262/discontinued-product-manuals.

You may also want to look at some of the schematics for the older SGC tuners. I think they had phase and magnitude detectors as well as forward and reverse RF power.

As far as we know, we were the first to automate it all with just the forward and reverse RF power sensors. It's now the standard method that nearly all the other companies use.

Dick,

LDG would be the only place that could fix it. Unfortunately, most of parts for that unit are no longer available (thanks Motorola, Xicor and Allegro to name a few).

It could be a bad display. Those are controlled by the processor, but if bad would give the appearance of the processor being bad.

I contacted LDG a couple of years ago and received a rather curt reply
that they no longer
supported that unit. And, I believe that most of the parts, possibly
excluding the display,
are still available.

5923. AT-11MP and Pegasus

From: k4mt
Topic: 5923 Message: 5923

I know the PT-11 was long ago discontinued but is it possible to integrate an AT-11MP inside the Pegasus or did the PT-11, as I suspect, have custom firmware making this idea impractical?

5924. AT-600Pro vs AT-600ProII

Hi,

I'm thinking about upgrade and wondering what are the differences between AT-600Pro and the new AT-600ProII tuners?

Stefan,

The only difference is the ProII has an interface jack on the back to go to the M-600.

Hi Dwayne,

Thanks for you answer. I have 2 more questions.

1. Does the ProII has still the KEY line problem?
2. Do you have plans to include additional controls on M-600 for Ant1 <> Ant2 switching and Bypassing the tuner?
Any "remote" tuner from LDG in the future?

Stefan

Stefan,

1) I don't know of any KEY line problem.
2) While it's possible, we don't have any current plans for it.
3) We've been looking at remote tuners for a while, but nothing to report right now.

5928. Remote LDG Outdoor Auto-Tuners

Yahoo group: LDG-auto-tuners (2010 — 2017)

Group,

With LDG auto-tuners become more prevalent, especially with the release of the new Pro versions, when do you think we will see added hardware for remote outdoor auto-tuner usage? The simple hardware configuration would seem to be an external plug in the rear of the auto-tuner that activates the unit's TUNE when a push-button is hit from inside your shack (of course, we'll need a wire/cable that runs from the remote location to the shack).

LDG can definitely capture a lot of the MFJ's external remote auto tuner market because of the continuing MFJ dismal quality control record (just check out MFJ's scores under "Product Reviews" on eHam.com).

73, Rich

Rich,

I know this might not be the solution you were looking for, but when I bought my ldg z100 pro II the folks at HRO told me that if I was not putting power to the antenna,I could just put the little guy in a water tight toolbox with the battery pack wired up and inline with the shack coax connection and it would auto tune with no issues. The battery draw would be minimal and because it had such a large number of memories it would hold all the settings you were likely to need. I know this was probably not designed this way, but I do know that others are thinking along these lines.

Food for thought.

George

5930. AT-1000 does not show correct power out

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2013-02-05 20:54:44 UTC
From: Randy B.
Topic: 5928 Message: 5930

I bought a new AT-1000 a few years back (gray box) for use with my Icom-718 and an AL-811H. Not long after I had it something went ka-blewee inside. It was under warranty so I sent it back. The return note indicated a bad connection somewhere inside. However, it has NEVER shown what I consider to be the correct power out on the scale. I finally bought another wattmeter to check the power output and according to the new meter the tuner is indeed showing way low on output. It seems to do ok on indicating the SWR but the dang thing caused me to burn out a choke in the AL-811H trying to get the wattage up where it should be. I don't trust this thing but it is all I have for matching on my long wire and I can't afford another tuner that will handle that much power. Has anyone else had this problem? Maybe I should have complained earlier but I have just been trying to make do and stay on the side of caution. You can't talk when your equipment is in the shop.

Hi Dwayne,

Back in 2012 while i was working on my TS-2000 tuner interface for AT-600Pro i found this KEY line issue:
Tuner is not responding to an external tune command (START line pulled down/released for 500mS) by pulling KEY low, requesting carrier as described in Tuner Interface Application Note.
We exchanged couple e-mails back then.
Now my question is this issue fixed in the new AT-600ProII?

Hi Dwayne,

There seems to be an increasing number of LDG AutoTuner users who have voiced a desire for some kind of remote operation.

How about forwarding this up the lines and see if it is feasible to implement an abbreviated or limited method of tuning AutoTuners ... something like was mentioned recently "... a simple method that enables one sitting in the shack to hit the "tune" button when the AutoTuner is someplace remote ..." Then may be later you guys can introduce a full-fledged remote autotuner.

That's what I did with a Z11Pro...put it in one of those cheap plastic ammo boxes that have the seal in the lid,run power through a pair of MFJ Bias-T's..It's been out there for a couple years now I think..There are pics in the S9 group of the setup.

Hi,

They are remote functions already integrated in AT600Pro - the radio interface.
Now I have TS-2000 followed by ALS-600 PA in my shack. Made interface box and now when i press TUNE button on TS2K it will bypass the PA, send 10W carrier and start tune on AT600Pro. There is just a small problem in the KEY line and the interface can't see when the tune is completed and i need to press again TUNE to end the processes.
This can be done also from the PC. On HRD screen I added <AT GO> and <AT END> buttons and now i can do this remotely.
Automating the tune process (bypass PA, send 10W carrier then tune) is important to me, because it is safer for my Tuner and PA and makes less QRM.

With the new AT600ProII, using the additional serial interface for M-600, new functions can be added:
1. Remotely switching between ANT1 <> ANT2 and switching the memory banks. Now i have external switch to change antennas and after every change i need to tune again, because the tuner does not know about that.
2. Bypassing the tuner when needed.

Thinking to upgrade to the new ProII series and adding this functionality.

CU on CQ WW RTTY WPX this weekend!

Stefan,

Since we don't have an interface for Kenwood radios for the AT-600Pro or AT-600ProII, that is an issue that we would not look at. So I doubt the 600ProII behaves any differently than the 600Pro.

It would be really cool if there were a f/w update to the pulse protocol to set bypass, ant 1 or ant 2 (positively set rather than swap). This would be a real bonus for remote operation.

Stewart,

We could look at that. However the tuner responds with what antenna is selected after the swap, so the smarts on the interface side should be able to handle that.

Maybe we could add a query function that would respond with the current antenna, Auto/semi mode and bypass/or not.

Hi Dwayne

Sorry to be dense, but looking at TUNER INTERFACE APPLICATION NOTE REV A
I can see the commands 80ms/550ms/2.5s, but it give no information
about the ant sel function (just says toggle bypass) but more
importantly it does not seem to specify the response code. Where
can I find this please.

I agree that it will normally be perfectly acceptable to remember
last state and move through the sequence, but I could not find a
definition of the responses.

The info for the serial interface for the AT-600ProII and AT-1000ProII is in the manuals section.

Topic: 5928 Message: 5942

Randy,
I don't have an AT-1000, but I have been using antenna tuners, including automatic and manual ones, for a long time. I think you are concerned that the tuner is not operating efficiently. This can be difficult to measure because the output of the tuner is a conjugate match to the load (antenna), and thus is at a complex impedance that a power meter will have difficulty measuring accurately. The easiest thing to measure is the temperature of the tuner. If it is not operating efficiently, then the difference between the input power and the lower output power has to be going someplace, and is most likely being dissipated as heat in the tuner. If it is not getting hot, then the power in is going out. If the VWSR at the input to the tuner is low, then the power meter reading at the input should be accurate (if the power and VSRW meters are working and calibrated properly). If your amplifier is having difficulty loading into the tuner when the VSRW measures low, I would recommend checking the amplifier out with a good dummy load to make sure there is not some problem in the amplifier itself. If it works well with a dummy load, but not with the tuner when the VSWR meter reads low, then you need to check out the accuracy of the VSWR meter. The scientific method is to check out each piece independently to isolate the piece that is not working correctly.

There is a method of directly checking the efficiency of the tuner I have used, but you need a second tuner, preferably manual. Set up the manual tuner with a dummy load and power meter on the input (transmitter) port, with the power meter directed to measure the power going into the dummy load. Next, connect a VSWR meter on the manual tuner's output (antenna) port, and drive it with a transmitter (low power is recommended). While transmitting, adjust the manual tuner to produce the mismatch you desire: 2:1, 3:1, etc. If you have an antenna analyzer, you can adjust to a specific complex impedance. After adjusting to the VSWR mismatch you want, connect the manual tuner output (antenna) port to the output (antenna) port of the tuner you wish to evaluate (such as your AT-1000). Connect a power meter to the input (transmitter) port of the tuner under test, and the transmitter to the power meter. Transmit and adjust the VSWR with the tuner under test (automatically for your AT-1000). When the VSWR at the transmitter is low, measure the power going into the tuner under test, and the power going into the dummy load from the second tuner. The ratio of these two powers is the efficiency of the tuner (both tuners combined, although I used a 1.5KW manual tuner so it should have been more efficient than the 100W automatic tuner I was testing).

Hope this helps!

Another good method is to measure the thermal losses - the heat dissipated by the tuner. You can use a properly sized cooler, put the tuner inside and measure the temp rise while operating. Then put inside a lamp and apply power until get the same temp rise. That is your power loss.
I will just open the cover and see how hot is inside. Compare it with 40W or 100W bulb and you will got the idea of power losses.

If you loose just 3db at 1KW, AT-1000 will have a red glow :))

Update.

Opened up my AT-11MP today and put a 27K in series with both meters.
Now I can adjust the preset to give 4.5 volts at the test points, with 100 watts. Now the power meter reads 100 watts, not hitting the end stop.
Now the auto tune works as it should.

Philip g7jur.

Stephan,

While the calorimeter method may be a good method to measure under low power conditions, it would not work at high power. When a toroidal core saturates, it becomes more inefficient.

If you accidentally saturate a core, then you'll get a sort of thermal runaway where the core get's hot, then becomes more inefficient and then becomes even hotter. If it gets too hot, it goes to a point to where the core will no longer have the original characteristics and the entire tuner will sub-perform.

The ARRL Labs did tests of what they thought were tuner efficiencies back a few years ago, but they only use resistive loads. We still don't even make a reference to that article because it uses completely non-real world data and is basically useless. We complained so much that we asked for our products to be removed from the test, but they refused.

There are ways to test the efficiencies, but since the tuner has over 100,000 combinations of Ls and Cs and covers 1.8 to 54 MHz, it may take someone years of data collections with all of the variables to find the true answer for a particular unit.

As a general rule, it's more efficient when it needs to match a load that is at 3:1 than it is to match a load at 6:1 and even better than one at 10:1.

Philip,

I question to a point about the modification that you have done. While it may work for you, the meter elements are driven by D/A converters, then converted to a current driver to drive the meter.

A more proper place to make any modifications may have been on the SWR circuit. The SWR circuit reads the forward and reverse voltages that correspond to the forward and reverse RF power. This is read by the A/D pins on the processor. Then the forward and reverse voltage is then used to compute the SWR.

If the proper reading were not being displayed on the meter, it's more likely an issue with the SWR circuit rather then the D/A circuits that drives the meter.

However, if you find your solution solves your problem, then that is fine with us.

Topic: 5947 Message: 5947

Can anyone help I need a Schematic for my AT-11MP.
I built it from a kit, but I now need to fix it and I have lost the Schematic I had for it.

Hi
I have a Yaesu FT-897D with a LDG AT-897 Plus.
I would like to use a bluetooth dongle to connect my computer to the radio.
I should have to connect the dongle to the AT-897 Plus computer port, so my question is: is the Computer port a full replica, so it can feed the power needed to the dongle?

Thank you for any answer!

Hi Dwayne.

Point taken. I have removed the resistors that I have added.
Applied 100 Watts and set FWD trimmer so meter shows 100 Watts,
Then set REV trimmer physically the same as FWD trimmer.
This same to work the best. Done the same why as the Z11.

Stefano,

Yes all pins pass through then the tuner is not tuning.

Topic: 5928 Message: 5952

Yeah is too complicated
I won't go it to physics to explain that calorimeter method is good to measure any kind of power losses.
My point was that power losses in this type of equipment can be very easily estimated, by observing the temperature inside the enclosure.
If losses are more that 50W you can feel them.
I don't think AT1000 will survive > 100W power losses inside without burning.

> > > I don't have an AT-1000, but I have been using antenna tuners, including automatic and manual ones, for a long time. I think you are concerned that the tuner is not operating efficiently. This can be difficult to measure because the output of the tuner is a conjugate match to the load (antenna), and thus is at a complex impedance that a power meter will have difficulty measuring accurately. The easiest thing to measure is the temperature of the tuner. If it is not operating efficiently, then the difference between the input power and the lower output power has to be going someplace, and is most likely being dissipated as heat in the tuner. If it is not getting hot, then the power in is going out. If the VWSR at the input to the tuner is low, then the power meter reading at the input should be accurate (if the power and VSRW meters are working and calibrated properly). If your amplifier is having difficulty loading into the tuner when the VSRW measures low, I would recommend checking the amplifier out with a good dummy load to make sure there is not some problem in the amplifier itself. If it works well with a dummy load, but not with the tuner when the VSWR meter reads low, then you need to check out the accuracy of the VSWR meter. The scientific method is to check out each piece independently to isolate the piece that is not working correctly.
> > >
> > > There is a method of directly checking the efficiency of the tuner I have used, but you need a second tuner, preferably manual. Set up the manual tuner with a dummy load and power meter on the input (transmitter) port, with the power meter directed to measure the power going into the dummy load. Next, connect a VSWR meter on the manual tuner's output (antenna) port, and drive it with a transmitter (low power is recommended). While transmitting, adjust the manual tuner to produce the mismatch you desire: 2:1, 3:1, etc. If you have an antenna analyzer, you can adjust to a specific complex impedance. After adjusting to the VSWR mismatch you want, connect the manual tuner output (antenna) port to the output (antenna) port of the tuner you wish to evaluate (such as your AT-1000). Connect a power meter to the input (transmitter) port of the tuner under test, and the transmitter to the power meter. Transmit and adjust the VSWR with the tuner under test (automatically for your AT-1000). When the VSWR at the transmitter is low, measure the power going into the tuner under test, and the power going into the dummy load from the second tuner. The ratio of these two powers is the efficiency of the tuner (both tuners combined, although I used a 1.5KW manual tuner so it should have been more efficient than the 100W automatic tuner I was testing).

5953. AT-600ProII power metering protocol

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2013-02-14 19:22:06 UTC
From: Stewart Bryant
Topic: 5953 Message: 5953

I am trying to work out if I can get access to fwd/rev
power from the AT-600ProII for my remote station operation.

Given that the meter skt provide an serial interface, it
seems plausible that the meter is actually receiving
digital signals from the tuner rather than analogue
signals. I assume the meter asks for a parameter
such as power, gets a value back and set the analogue
display accordingly.

So that begs the question of whether I am correct in
my deduction of how the meter works and if so whether
the power protocol (as opposed to the tuner control
protocol) is available.

I would be prepared to sign an NDA if required since
this is only for personal use.

I traded some equipment and got this at-11mp in the deal i was so excited. I have a un-tuned antenna; it has a 35' Ladder line with 45 long wire each side and no balin. SO I fired it up to see how it would do. it clicked made lots of noise and i thought the chatter was bad so i turned it off. thinking i made a making a mistake. then read it was noisy. but now it wont do a thing. I opened it up and nothing is burned. so i thought i would just need to have the memory reset because of the new location.

I know this is somewhat vague. Are was this a discontinued for a reason.
If you don't mind give me some steps to walk though. The manual dosent say what to do when things don't work....well that's not true they do say call the company. They must never have problems.... :)
I heard good things and want to keep it if it works.
Thanks
Dean

They make a lot of racket. Turn your power down to 5-10 watts and let
it tune. If after a minute or two it doesn't find a match, it probably
isn't going to. Be sure to monitor with an SWR bridge between the radio
and the tuner. If it doesn't tune, you might have better luck with a
balun between the tuner and the antenna. I'd try a 4:1.

Jim.

Sometimes I've had mine stop working. I've had to remove the power by disconnecting the power plug. Since you've had it open, I assume you've already tried that. You have the switch in the auto position, have the transceiver in am or cw and you have output showing on the swr bridge and the swr >2:1? It should be tuning at that point. You might try to work the cap and/or ind up and down and see if they are doing anything. Other than power/reset I can't help.

Jim.

Thanks for your reply's
Nothing in the manual has any mention to a reset procedure = done
Power removed = Done
Manually switching caps up and down I would go up and down to where it would stop clicking then take it all the way back = Done
So it does manually click when I go up and down has a limit both ways = done
CW or FM transmission = I don't have the right CW plug for my transceiver so I will do this test after I get the plug. If its that simple I'm embarrassed. So that's why I asked. I know in all the excitement of new setups I overlook some obvious steps. New radio I don't even know if I was transmitting the needle barely moved.
So this would make since it did have enough power to tune.

Then as suggested I will call LDG for chip chasing.....

Thanks Again.

5964. Interfacing IT-100 (Icom specific tuner) with a Yaesu FT-857D txvr?

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2013-02-18 21:01:24 UTC
From: geoffro316
Topic: 5964 Message: 5964

I have an Icom IC7000 and IT100 LDG tuner setup at my home QTH running on an end fed long wire but I want to try and find an interface lead to connect the IT100 to the mobile rig in my car which is a Yaesu FT857D.

I mainly use 40m on my 857D in my car and have an Opek HVT400B multiband tapped antenna which I leave permanently tuned to 40m. I did a bit of an experiment last night where I connected up the Icom IC7000 and IT100 tuner in my car to see how the Opek HVT100B antenna would go being set for 40m but being tuned to other bands with the tuner (I drive 2 1/2 hours to and from work everyday and spend most of my on air radio time during my drive - drive on the M1 Motorway between Brisbane and Gold Coast Australia so I just set the cruise control for 110kph, aim the car straight up the motorway and settle in).

I was initially looking at a screwdriver type antenna but the ATAS120 seems to be a little untrustworthy from what I've read, the Diamond SD needs to be "fiddled" with too much to tune (have to key the PTT and the tune buttons at same time - remember I'm driving my car here) and the Codan type auto tuning antennas are huge (I drive a Holden Commodore sedan and would have to trunk mount the antenna as I don't have a tow ball). Also, due to budget constraints I've come up with an alternate option of running an auto tuner inside the car. I know it's a massive compromise, but I only have about $300AU to spare on my mobile auto tune solution at the moment!

When I tried my IC7000 and IT100 tuner in the car last night I was quite happy with the tuning results! I couldn't get the HVT100 antenna to tune down past 6500.0 kHz which means I won't have 80m :(however it "appeared" ok on everything else from 6500.0khz up to 29000.0khz. I also tried moving the "wander lead" and adjusting the antenna for various other frequencies before re--tuning again and the 40m setup seemed to work the best. My only negative find was that I couldn't tx more than 30w, even on the 40m band which the antenna itself was tuned to with the IT-100 tuner connected! The rig would tx 100w without the tuner connected on 40m, but not with it? It was raining heavily at the time so maybe that put the SWR way out or it was drawing too much current (I wouldn't think the tuner would draw that much extra - vehicle motor turned off)??? Obviously the antenna will have some degree of deafness as its a massive compromise to what I should really be doing (pulling over, changing the antenna "wander lead" to the next band and driving off again) but on the Motorway I don't really have that option plus, I flick through the bands on the fly anyway.

QUESTION 1
Is the LDG IT-100 tuner suitable to mount in a vehicle (road vibration, some minor dust perhaps)?

QUESTION 2
Can I buy an adapter to connect the LDG IT-100 (wired up for Icom) to the dedicated tuner jack on the Yaesu FT-857D? And if so, can I just use the TUNE button on the Yaesu rig as opposed to the button on the tuner (tuner would be mounted under the seat initially for experimental purposes - I realise it should be mounted as close to the antenna as possible so I may be able to relocate the radio body into the trunk along with the tuner and shorten

the coax down to about 500mm to 1000mm as it will be)

QUESTION 3
If the IT-100 tuner is successful for my project, I'd eventually purchase an LDG tuner dedicated to the Yaesu FT857D. Are the Yaesu LDG tuners suitable for vehicle mounting?

QUESTION 4
If this sounds like it won't work for me, does anyone have any other cheap options to operate mobile multiband and without stopping? As I've mentioned, cash is a problem plus I can only boot mount an antenna so can't use anything too big or heavy (my HVT400B is very light, and 1700mm tall and have had that mounted successfully for about 8 months or so).

ANY ideas or suggestions are most definitely welcome!

73's, Geoffro VK, Gold Coast Australia

Stewart,

Some of that conversation took place off the group.

We haven't and probably won't release any more info other that what is published in the document. Of course, you are free to examine the data in real-time and figure it out.

Basically, it's raw buffered data from the forward and reverse power sensors. There is really not much you can do with it.

Dean,

Pretty much none of the LDG tuners have a "master reset". There are very few variables stored that the user has access to that there really is no need for it.

If the processor "gets lost", then pulling the DC from the back is the only reset. If you get frequent lock ups, then you most likely have an RF issue getting into the ground system.

Paul,

The SR8T has a different protocol than the other Alinco radios. So there are no current LDG tuners that will interface to it.

This is somewhat noted on our Alinco interface cable page:

Hi,
I have a sgc 230 tuner which works very well with my 9 foot whip on the Jeep.......
Thought i wouLd try my LDG Z11 PRO in the Jeep as well......
Very short coax from tuner to whip base it works well on 5 megs/7 megs/14 megs and 28 megs...not tried it on 3.5 yet

5970. Lock ups and other weirdness.

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2013-02-20 02:43:36 UTC
From: Furliips Stardust
Topic: 5964 Message: 5970

I have an LDG Z11 Pro II tuner.

I'm using a 102' doublet antenna fed with 40' of 450 Ohm line.
With an Icom IC-761 transceiver and Kenwood SM-220 station monitor.
My ham shack is on the second floor 25' away from a "real" ground.

That being said, I've been changing things here and there over the past year to get things to work smoothly and reliably.

1. A section of 3/4" copper water pipe the the rear and right side of the station with all the equipment bonded to a common ground.
2. #4 AWG wire from that to the base of the tower and the tower grounding rod.
3. Ferrite cores on the USB mouse and USB speaker leads to the PC.
On Xmit, the mouse would freeze and recover a few times before totally locking up. And I would get hum in the speakers.
4. Using a 9:1 choke balun instead of the 4:1 balun between the tuner and the feed line.
Getting rid of the built in 2.25:1 SWR from using the incorrect Balun makes the tuner's job easier.
5. Running the LDG tuner off of a "hard" 12 volt supply (An Astron 30 Amp).

Having done all this, I've managed to get the system to work very smoothly and reliably.
Until a month ago. Suddenly the Z11 Pro II would decide in the middle of a PSK contact to go through the entire tuning sequence again.
Head scratch, "That's odd, now what?"
Review things and ask myself, "What changed?"

Oh, I added a very nice HP All in one printer/scanner, copier/fax to the shack computer. On a 6' USB cable.
Was the Printer, USB cable and printer power supply cable acting like a floating counterpoise? Perhaps, but it was definitely a problem.
Adding a snap-around ferrite core to the USB cable at the PC end solved the problem and the system is back to it's smooth reliable self again.

So, the bottom line, is stray RF getting coupled into things and via some of the least expected places will cause some truly odd results.

You gave a lot of data, but you missed one very important item: the frequency.
Also, for my curiosity; Why 102'? That isn't resonant in any Ham band, is it? I know that's the length of a G5RV, but the rest doesn't match

Bill--W4BSG
It's called a non-resonant doublet. It was quite popular back in the '30s up through the '50s.
The problem with the G5RV antenna is the claim that it doesn't need a tuner and the 40' section of balanced feedline is terminated directly to a piece of 50 ohm coax.
The 102' doublet length and 40' feedline are actually an optimum value. WITH a tuner, the antenna WILL tune up nicely and radiate on 80-10 meters.
Shorting the feed line, and inserting about 65 uH of inductance with it, the antenna will also tune up on 160 meters and acts like a top loaded vertical.
Case in point, working RA3DA in a pile up, from Central TX, competing against a bunch of East Coast stations running a LOT of power into beam antennas, I didn't get him on the first try, but I did get through and got a 57 signal report running 100 watts.

Thanks. I do know about doublets, dipoles, and the "Real" G5RV, as well as some snippets of other antenna lore. However, I am curious about the use of the word "Optimum". In Engineering studies, this implies evaluation with regard to some defined criteria. Can you clarify and tell me also where this evaluation can be found?
Thanks-- Bill--W4BSG

"Optimum" in this context means a serendipitous choice of feedline and dipole length which results in the impedance matching device being presented with something which is easily transformed to 50 + j0 Ohms impedance so that the transmitter can deliver power on the bands of 80 through 10 meters.

This is not a "Singular Point" - other choices can result in similar results, and, to some extent, it is an oxymoron because with suitable impedance matching parameters, practically any impedance can be transformed to 50 + j0.

We'uns is amateurs after all. Only a few of us are Engineers, and even fewer of us hold Electrical Engineering Degrees with specialization in Radio Frequency Applications.

I'm sure there are several learned discussion of a 102' dipole on L. B. Cebik's (W4RNL SK) site: http://www.cebik.com

I'll leave it to the student to find the exact location or locations within that site

From a 1938 ARRL handbook:

The lengths given for non-resonant dipoles fed with open wire line are basically:
For 80 meters and up
1/2 wave length fed with 1/4 wavelength.
I.e.: 137' doublet with 65' of feed line
And for the "shortened" version:
3/8 wave length fed with 1/8 wavelength.
1.1: 102' doublet with 40' of feed line.
Note that the shortened version, the doublet length + the feed line length = 1/2 wavelength.
You can cut the numbers in half and use them on 40 meters and up.
Add a 1/2 wavelength (65') of feed line, 85' overall feed line length, since 20' is a bit short.

Now of course, "back in the day" transmitters were push-pull and link coupled, the antenna tuners tended to be balanced to begin with, so "the proper balun" wasn't so much of an issue.

Please clarify your comment

"Add a 1/2 wavelength (65') of feed line, 85' overall feed line length, since 20' is a bit short."

This is the best explanation I have seen for the classic 102 foot doublet.

The 102' doublet can be scaled down to 51' and will cover 40-10 meters.
The problem is the feed line scales down to 20' and that's kind of short.
So, you add a 1/2 wavelength of feed line, 65' at 40 meters, to lengthen the overall length of the feed line to a usable value.
Being a 1/2 wave length, and multiples there of at higher frequencies, it tends to be transparent to the overall matching of the antenna.

Mike,

I'm using the LDG Z-100 with the Chameleon Antenna HYBRID-MINI and the Chameleon Antenna EMCOMM II. All of them tune from 6M to 160M easily. Make sure that you cable behind your radio is TOTALLY inserted inside and not just partially.

The HYBRID-MINI can be used portable, mobile and base station while the EMCOMM II can only be used base station and portable.

Chameleon Antenna HYBRID-MINI:

Mike,

one more thing: Make sure to use at least 15' of good quality coax cable. I'm using RG-8X or better. Ground you radio and tuner to earth and avoid having your coax cable to run and create loops randomly on the floor.

Now that spring is around the corner, we're blowing out the 31 foot fiberglass S9v31 old stock antennas for $65 each at www.cheapham.com. These are the old style with the metal screws that hold each section together. They cannot be used with the polymer clamps.

They are also eligible for the Free Balun Rebate directly from LDG. The rebate form is included with the manual when you purchase the antenna. There are only a few left and will not last this long at this price.

From: Avery
Topic: 5982 Message: 5982

My KT-100 won't tune using the AT button on my TS-480SAT. Both were purchased recently. I think I have followed the instructions correctly, and I updated the TS-480 firmware to V106. The KT-100 is connected to ANT 1 jack, and menu #27 is set to At1. But when I press the AT button, nothing happens. When I hold the AT button, after a second the display momentarily flashes "R < AT > T", and the red LED on the KT-100 flashes four times, but no tuning took place. I tried reducing the power to 10W, then transmitting CW while holding the AT button, and the KT-100 does tune just fine (same as when I press the front panel tune button, the red LED comes on while I hear the relays chatter, the red goes out and the green LED comes on). With my antenna, the SWR goes from about 3:1 to about 1.1:1 according to the TS-480SAT display. But, the "AT" area of the TS-480SAT display remains blank, unlike when I use the internal tuner (i.e., I get the "R < AT > T" icon). I got the KT-100 to use as a remote tuner, so I have cut the supplied control/power cable to splice in longer wires, and I have double and triple-checked the wiring for correctness. My question is, what else can I do to get this KT-100 to work "transparently" (i.e., just like the internal tuner)? Please help!

Thanks & 73,

Topic: 5983 Message: 5983

Hi All

I have recently purchased an LDG Z11 Pro2 auto atu for use with my Yaesu FT-897D and am getting used to using it. One of the things I have noticed about the tuner is it seems to take a long time to tune some of my non-resonant wire antennas. For example my 40 foot end fed wire took about 6 seconds to tune up on 40 metres, where the internal ATU in my Yaesu 450D tunes it much quicker probably around 2 ☐ 3 seconds. I am concerned therefore that I may damage the output/PA on my radio during the tuning process as the 897 output displays the "high swr" message almost constantly during the tuning cycle. I do turn the power right down to minimum (5 watts) but is it possible to cause damage by using a tuner in this manner?

I realise this is a pretty basic question but I would just like to get some opinions from the group.

Thanks and 73

Paul 2E0PJY

I wouldn't worry too much about the high SWR indication. That is just
telling you the fold back circuit in the radio is working and is normal
when using an auto tuner. As the tuner tries all the different LC
combinations some will be over the 3:1swr that triggers the indication.
I've ran my 857 for about 10 years with it doing that and I never turn
the power down either.

5985. Z-817 CAT problems

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2013-02-27 18:59:48 UTC
From: wildergeek
Topic: 5985 Message: 5985

I recently emailed LDG about my Z-817 tuner not working with my FT-817 radio. They advised me that there wasn't much I could do and that they would check it if I sent it in.

Since that email, I ran a little test and discovered that the tuner actually works fine if I use it manually by switching the radio mode to AM or DIG and keying up when I press the tune button. I also discovered that the Z-817's CAT pass-through works so the CAT problem is not in my radio.

Has anyone else had problems with the CAT functionality in the Z-817 and is there anything I can check inside before sending the unit to LDG for repair?

Yes, I did confirm that the baud rate was set to 38,400 on the radio.

Advice will be greatly appreciated.

Hi

Make sure VFO-A and VFO-B are identical !!! That might not be 100% required but it helps a lot. Long press on VFO A=B button in the quick menu until you hear a beep.

If one of the VFO's is set to FM in the 100 MHz broadcast band for example, tuning recall/full tune cycle will not work. I can repeatedly prove it on a Z-817H and two FT-817's. The symptoms are no tune, no transmit during tune, radio not going to PKT mode, whole cycle takes < 1sec, and red and green LEDs keep flashing in sequence for a while afterwards.

Setting VFO A=B is an easy fix, in case you were in the same situation as I was. It wasn't obvious to find because I rarely (read never) use VFO-B on the FT-817... but it works great.

5987. Is there a reset proceedure or a basic start for an LDG Z-817H tuner?

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2013-02-27 23:23:46 UTC
From: ki6tsf
Topic: 5954 Message: 5987

Hi,

After switching antennas definitively, is it required to ALWAYS
force a full tune cycle for each frequency you will be using, at least
for the next 2000 iterations? (to ensure all the previous settings are overridden).

I assume all settings in memory for the previous antenna might be wrong, and TX after a simple memory recall tune might damage the radio final (esp. with 100% duty cycle digital modes that last minutes).

If one forgets to do a full tune cycle and does a memory recall instead after switching to a new antenna, a wrong match could be fatal for the final. Since there are 2000 settings in memory, chances are high that might happen well before 2000 iterations.

Is the above reasoning correct or did I miss something?

Is there a way to wipe out the memory or to buy a new chip from LDG (+ some spares for later) (Z-817H model)? I guess that would be a perfect solution?

Thanks a lot!

There may be too much RF on the braid of the coax and/or hitting the tuner. It messes up the tuning circuits and the tuner keeps recycling. I had the same problem until I put a choke on the feed line.

5992. IC-718 & AT-11MP

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2013-03-01 20:36:54 UTC
From: martynwhyte
Topic: 5992 Message: 5992

Would I be correct in assuming that to interface my IC-718 to my AT-11MP I would require the services of an IC-PAC lead.
If I am correct once this has been done I then need to change the setting in the 718 menu to AH-4 in order to complete the cycle thereby being able to tune via the radio!

Regards,
Martyn-MM0XXW

5993. LDG tunners on horizontal loops

Hi Jody,

I have never had an issue with the LDG wide tuning range PRO models in dealing with my 500 foot of wire Delta Loop during the last 4 plus years no matter being wet or iced, it resonates just above 2Mhz near my lowest MARS frequency used for ALE.

The AT200PC is in daily use on that antenna, basically the same tuner as the AT200PRO which I also have, in addition I have used the new AT600PROII with no issues.

This particular loop consists of less than 50 feet of RG-214 to a ByteMark 9:1 HB-450 balun with heavy braid connection to 8 ft. 5/8 ground rod with 30 feet of 450 ohm 12ga. ladder line to a Ladderlok feeding the 500 feet of jacketed 12ga. wire which free floats through one end of Alpha Delta DELTA-CIN end-insulators where the other end is connected to the supporting 5/8 inch dacron rope. The entire antenna system is completely insulated from the elements. Here is a .PDF on the antenna, not much more details then I just provided:

<http://www.n2ckh.com/ANTFARM/N2CKH_2Mhz_Loop_Antenna.pdf>http://www.n2ckh.com/ANTFARM/N2CKH_2Mhz_Loop_Antenna.pdf

Jody,

I have used LDG and SGC autocouplers on all of my big horizontal loops for years, indoor loops and outdoor loops.

They all work fine, but I suspect that you're experiencing an "impedance weirdness" common to most antennas that are used on multiple bands. Mine is 45 kHz on either side of 3.8 MHz... :)

For every antenna (dipole, loop, etc) and feed line combination, whether coax of open-wire line), it seems that SOME FREQUENCY (or some frequencies) among the many that we're asking the system to match, present impedances that give the autocoupler a real challenge.

Like what you're experiencing, a particular setup may tune perfectly everywhere except one part of one band. It can be frustrating, but it's not unexpected considering the huge range of potential impedances we encounter when trying to match a single antenna from dc to daylight.

Possible solutions include adding (or subtracting) feed line lengths, adding or subtracting wire element lengths, adding L or C to the antenna side of the tuner (perhaps switchable, to address only the "problem area"), adding 4:1 or 9:1 baluns or ununs to the antenna side of the tuner, etc. There are probably more methods out there.

Of course, by fixing the problem area, you usually move the "weirdness" to another spot, but if that spot is outside the ham bands or on a ham band you're not interested in -- problem solved!

I prefer the "adding or subtracting feed line lengths" method as a first resort.

Other list members may have their own favorite techniques to contribute.

You didn't mention which, if any, balun you were using.

As I've mentioned repeatedly, if you're using 450 ohm ladder line, everyone is happier if you use a 9:1 balun.

From: k2lrv
Topic: 6000 Message: 6000

So I picked up one of the S9V31's that were on clearance. I am going to submit for my free balun, and I am wondering if there is any recommendation on which one is "best" to buy. I currently have eht RBA-1:1 and RBA-4:1, and I am considering getting the RU-4:1 just because I don't have it, but if it is on no use with the V31, then I will get a second of one of the other ones.

Thanks,

Lou

> I am surprised , since a MFJ - 993B will tune this antenna on all .
> Jody

I am using the Z11 Pro with a 60 foot half wave open loop, a dipole bent into a rectangle, and it tunes fine on 40-10. It also tunes on 80, but I've never tried to make a QSO there.

I fed the antenna with RS 300ohm TV twinlead, into a MFJ 4:1 balun, which is attached to the tuner. I find it loads pretty well and the antenna seems to work OK. I've worked Europe and Australia on 30, Canary Islands on 40, and have worked DX on other other bands.

The antenna does have some strange directional characteristics, like it doesn't do very well to the west on 20 and seems to have trouble toward South America on 15.

Hope this helps.

Lou,

Check the S-9 Online Manual- page 3 (it may be different than the one you got) - http://www.ldgelectronics.com/assets/manuals/S9v31%20Manual%20Rev%20B%20BW.pdf

For 40 meter monoband use, a 1:1 choke balun.. Use the LDG RBA-1:1 for up to 200 watts

For Multiband use, a 4:1 "Unun" is recommended.. If using 200 watts or less, you can use the LDG RU-4:1 Unun.

So it depend on how you want use the antenna..

I also had a RBA-1:1 & RBA-4:1 baluns so ordered the RU-4:1 Unun so I could experiment a bit. It has been too darn cold for playing with antennae in this part of Canada so I have left that project until it warms up..

Thanks Dwayne, I ordered the lead which is now attached and everything is working as it should via the radios' tuner button!
It's a super tuner, quick as a flash tuning my Doublet and I'm not really finding the lack of memories an issue at all in fact I prefer it to my last one which was the AT-100ProII.

6007. Fixed, Re: KT-100 won't tune, please help!

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2013-03-10 05:59:22 UTC
From: Avery
Topic: 5982 Message: 6007

When I extended the cable from the KT-100 to the TS-480SAT, I inserted a box with RF chokes and bypass capacitors. I built a new cable without the RF chokes, and the KT-100 works just like the manual says it should. The lesson is that the two control signals have considerable bandwidth, and a filtering approach must be strictly common-mode, not differential mode, such as a ferrite bead over the whole cable. My new cable uses CAT-5E cable, and I was careful to properly pair the signals. CAT-5E has 8 conductors in 4 pairs. Each pair has a different color with a solid color wire paired with a striped wire. I connected all four striped wires to GND, two solids to +12V, and the other two solid wires to a control signal (TT and TS). Since the wire gauge is only 24AWG, doubling the power line is a reasonable precaution, and pairing power and signal each with a ground line brings the benefit of the full signal integrity of the CAT-5E design. Actually, what I did is to take two CAT-5E patch cords that had one broken end (RJ-45 modular plug), cut off the broken end and wire it to the antenna tuner molex connector for the TS-480SAT end, and to the 7-pin mini-DIN for the LDG KT-100 end, and use an RJ-45 two-socket union in the middle. This way, I can use standard RJ-45 connectors and CAT-5E cable to make up any length cabling between the TS-480SAT and the KT-100. Also, I wrapped the CAT-5E cable around a 2.4-inch diameter toroid core for RF isolation. So, ultimately my problem was caused by my jumping the gun with an incorrect filtering scheme.

>
> My KT-100 won't tune using the AT button on my TS-480SAT. Both were purchased recently. I think I have followed the instructions correctly, and I updated the TS-480 firmware to V106. The KT-100 is connected to ANT 1 jack, and menu #27 is set to At1. But when I press the AT button, nothing happens. When I hold the AT button, after a second the display momentarily flashes "R < AT > T", and the red LED on the KT-100 flashes four times, but no tuning took place. I tried reducing the power to 10W, then transmitting CW while holding the AT button, and the KT-100 does tune just fine (same as when I press the front panel tune button, the red LED comes on while I hear the relays chatter, the red goes out and the green LED comes on). With my antenna, the SWR goes from about 3:1 to about 1.1:1 according to the TS-480SAT display. But, the "AT" area of the TS-480SAT display remains blank, unlike when I use the internal tuner (i.e., I get the "R < AT > T" icon). I got the KT-100 to use as a remote tuner, so I have cut the supplied control/power cable to splice in longer wires, and I have double and triple-checked the wiring for correctness. My question is, what else can I do to get this KT-100 to work "transparently" (i.e., just like the internal tuner)? Please help!

Date: 2013-03-13 22:40:11 UTC
From: traceybo@...
Topic: 6008 Message: 6008

I just got a new AT-600Proll and tried it on 2 different antennas, that work well but on different bands. What I am experiencing is the tuner goes through the tuning sequence, does tune a fairly low SWR, about 1.4 or so, but them if you transmit more than 5 seconds, the swr starts rising, and it retunes, and repeats over and over. Just won't stay in one place. The swr goes way up, from say 1.3 up over 3. I have an 80 meter dipole cut for CW, I am trying to use up high, 3.9 and a 40m dipole I am trying to use on 10m. For right now I am just running straight, because it swr is better bypassed.

I figure something is loose, but since it is brand new, I am afraid to take the cover off, for fear of losing warranty. Or maybe I just am not understanding something. I tried to contact LDG via the website email last week, but haven't gotten a response. Today I just ordered another tuner, since I need one for a portable trip next week, and I can't return this one, but I am wondering if I should risk opening the thing or just send it back for repair.

What does everyone think.

I've run into some situations like you describe. I think RF is getting into the tuner.

I tune for the low SWR like you and then put the tuner into semi-automatic mode. No more retuning and all is fine for me.

Good luck.

I don't know what antenna you are using, however if you have some traps in are using capacitors this can be a symptom of the capacitor getting hot and changing value. I have had this in the past with my Butternut antenna.

Hi Chuck,
The LDG tunes up okay on quite low power or high power
am fm cw but when i am talking on ssb in continually tries to retune
itself.......have 2 of these they both do the same thing
The Clansman 321 set with a transistor linear also does this but its
more alarming because i believe the swr protection is poor on this
amplifier......2 watts in 200 watts out ssb.

Do you have an RF chokes on the feed lines?

RF can travel back down the lines and those will affect the onboard SWR calculations and send the tuner into a death loop like you are seeing. The CPU then sees a hi swr and sends the tuner into a retune situation.

What happens if you turn off the automatic tune in the tuner and then watch the SWR on the tuner with it's built in SWR meter?

I have chased so many weird tuning issues on both my home, remote and car and I refused to believe it was a choke issue. Of course, the mobile was worse. Just adding some type 43 chokes solved so many problems.

This is not the time to say 'not me' because I don't have any chokes lying around. :) Order 10 or so and you'll see the difference. They aren't expensive and they will actually also help your receiving.

Jim:

Should be a good rig. Real green stuff! Hope to catch you on the air sometime or perhaps at Dayton if you go there (Flea Market 2401).

Sounds like you're getting good input on your tuner issues. Hope you get that sorted out. Most of what I've seen like this is either stray RF getting back into the tuner, bad transmitter generating a lot of off frequency garbage, bad or marginal connections, things touching the antenna and such. Also have seen issues with some of the LDGs being sensitive to even low-level stray RF.

Good luck with it.

6018. RE: [LDG-auto-tuners] Re: AT600PROII Continuously retunes

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2013-03-14 18:10:46 UTC
From: Will Rogers
Topic: 6008 Message: 6018

Hi!

I have the 1000 watt version of the LDG tuner; there is a setting to turn off the automatic tuning on mine. It is recommended by LDG to set it up that way. It does, however, require that I press the tune button on my rig or tuner when I change frequencies. Once you have tuned a frequency up, it only takes a split second to tune the antenna. I am using a 92 foot ladder line fed inverted v on 80-6 meters.

Hope this helps!

73

Will Rogers

Do not of course tx with 200 watts into the LDG

The antennas are both just standard wire dipoles, 80m is 64.5 feet on each leg, 40m is 33 feet each leg. Fed with RG8X, Kenwood TS-480, 200w. Antennas are 40 feet up. phenolic on the end, tied to paracord.

The swr is really moving, if you key up in CW, the needle moves from 1.4 to over 3.5 in about 10 seconds. Then it starts retuning. If you do that with the tuner in bypass, on a freguency where it swr is lower, say 2:1, it sits still, constant SWR.

I am almost positive it is the tuner. My choices therefore are simply to sell it, I have only had it 3 weeks, Gigaparts won't take it back. Send it back, since LDG says on their website you don't need an RMA.

I have gone ahead and ordered another brand tuner, sick of messing with it. Got a manual versa tuner which will handle the 200w.

Anybody want to buy a 3 week old tuner?

Bill

> >
> > I just got a new AT-600Proll and tried it on 2 different antennas, that work well but on different bands. What I am experiencing is the tuner goes through the tuning sequence, does tune a fairly low SWR, about 1.4 or so, but them if you transmit more than 5 seconds, the swr starts rising, and it retunes, and repeats over and over. Just won't stay in one

place. The swr goes way up, from say 1.3 up over 3. I have an 80 meter dipole cut for CW, I am trying to use up high, 3.9 and a 40m dipole I am trying to use on 10m. For right now I am just running straight, because it swr is better bypassed.
> >
> > I figure something is loose, but since it is brand new, I am afraid to take the cover off, for fear of losing warranty. Or maybe I just am not understanding something. I tried to contact LDG via the website email last week, but haven't gotten a response. Today I just ordered another tuner, since I need one for a portable trip next week, and I can't return this one, but I am wondering if I should risk opening the thing or just send it back for repair.

Bill:

I hate to say it, but this doesn't sound good. Something in the path is having a problem. Since it doesn't happen when the tuner is in bypass, it has to be a relay contact, trace, solder connection, or component inside the tuner.

What does the tuner smell like? Have you opened it up to see if there's anything obvious?

Price?

Yes, they have a website contact option, say that is the best way, phone calls take up to 5 days. I put in the captcha code thing and all. Nothing, tomorrow make a week.

Yep, that is the page I used. At this point, Gigaparts shipped another brand tuner today. They said LDG wouldn't let them take it back. I asked Mike what else, he told me a versa tuner would handle the 200w, It was cheap, I bought it. I have a trip portable coming up next week, so I needed something that would work. The only bad thing is, the versa tuner was larger, and I have to backpack it part of the way.

Doesn't sound like a tuner issue.

Sounds like RF feedback.

LDG typically answers within a few hours, so something must be amiss
with the fellow who typically monitors this reflector.

72/73 de n8xx Hg
QRP >99.44% of the time

p.s. I'd guess it was RF getting into the tuner, if it were mine. Did
you try replacing a jumper coax or connectors on your coax?

Doesn't sound like a tuner issue.

Sounds like RF feedback.

Does it on two entirely different antennas with separate coax feeds. Swr is steady without tuner.
Thanks,
Bill

Topic: 6008 Message: 6033

RF Feedback is a very fickle thing. You'll find that a basic analogue SWR meter is much less susceptible than those in the LDG tuners even with different feedline.

In one example I had with the mobile, I changed everything at least twice and I could not get 40M to tune correctly with the autotuner for the screwdriver antenna.

The moment I added chokes to the DC control lines and to the RF cables at both ends, all my problems ended. The designer of the antenna controller kept telling me the same thing I am passing on to you. I thought the auto controller was junk.

On a lark, after weeks of messing with it, I decided to listen to him. I spent about $10 on some RF chokes and it has worked perfectly ever since. Since then, I have added chokes to most feedlines in the house and the remote base (at both ends of the feedline) and my stations have never been so stable.

I can create your problem on my Windom at my house station by removing the chokes at the tuner end when I'm on 40M (I don't have a ground rode due to the station setup). The tuner hunts all over. When I put the chokes back on, the problems go away.

Rather than sell your AT600ProII, find some type 43 chokes and give it a try. I know that it seems like big pain in the a** to give this a shot, but I bet it solves your problems.

BTW, this is the article that also convinced me:
http://www.yccc.org/Articles/W1HIS/CommonModeChokesW1HIS2006Apr06.pdf.

My 2 cents anway,

73 de Mike va3mw

6034. Re: AT600PROII Continuously retunes

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2013-03-15 12:02:45 UTC
From: traceybo@...
Topic: 6008 Message: 6034

I am willing to try that, but it isn't just the retuning, the swr moves, not just on the bar graph, but on the Kenwood, and on an inline meter as well, yet no movement when the tuner is bypassed.

The sequence goes like this exactly, in case I am missing something.

Find empty freq, put Kenwood in cw mode, 20w power, tuner in bypass, key up, un tuned swr reads 3:1 on Kenwood, same on inline meter after tuner.
Take tuner out of Bypass
Hit function auto, key up in cw, tuner tunes right down to 1.3:1
Hit function auto again, to prevent retune
Turn power up on Kenwood to 200w
Key up Kenwood set in CW, after 3-4 seconds, swr on Kenwood starts rising, tuner swr rising, analog swr meter forward dropping, reverse rising. After about 8 seconds swr reads higher than 3:1

If I left the tuner in auto tune, it starts tuning again when you pass the threshold, about 1.7, and tunes again. I don't let that happen at 200w, but have let it at 100w. It will go on forever, finally never achieving a good tune.

With the tuner bypassed, the swr never moves more than .1 on the analog meter and the Kenwood doesn't show movement.

Perhaps that is a better description. It does seem like if I let it tune, and then never transmit but ssb, and very short intervals, the tune holds. Power seems to be what causes the problem, but I thought the tuner could handle 200w forever.

And the offer holds, I paid 359 at Gigaparts February 8th 2013, will take 250 and free shipping with copy of gigaparts receipt. As is of course. But not a scratch on it, original box and manuals intact.

Thanks,
Bill

Don't know if you've already tried, but call them on the phone.

Whenever I've had to do that, I usually have to leave a message but they
have always returned my call.

6036. Yaesu tuning prorocol

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2013-03-15 13:10:18 UTC
From: k2lrv
Topic: 6036 Message: 6036

I have posted this question a couple of places, but seems nobody has done this. Has anyone ever reverse engineered the Yaesu tuning protocol used for their external tuners (i.e. FC-40).

I know that the LDGs will work fine in the Auto mode, but part of me would like to just be bale to push the tune button on either one and have it tune.

I have asked Yaesu tech support a couple of times and have gotten no response.

I have experimented a bit, and I have get my FT-950 to "think" there is a tuner present, but I assume there is must be some sort of handshaking that goes on because pressing the tune button does nothing.

6037. Re: [LDG-auto-tuners] Re: AT600PROII Continuously retunes

Mike,

Thanks for sending this email and attachment. I never realized the extent you can go to eliminate RF from a QTH. Great article. I have had an increase in noise emerge in my shack my cleaning up the shack and moving items around. It is pretty bizarre that by moving my power supplies, computers and monitors around my 20m noise went from S3/4 to S7/8. I am now hunting and trying all sorts of things. I think a strong program of ferrites like suggested in the article might save my bacon.

Thanks for sharing!

Which tuner are you using? There is a problem with some that lets (should I say encourages) local noise that comes in on power and control lines to be coupled into the RF path inside the tuner. Your symptoms are exactly as expected for that.

Bill and All:

It's exactly because of the symptom that SWR starts low and begins rising only when the tuner is not in bypass and has a tuning solution at low power that this is clearly not a stray RF problem and why I believe it's an internal problem with the tuner.

Chuck,

I use the LDG 1000AT with a Ameritron 811h and also an autotuner that is internal to the SPE 1K.

Keith:

Here's what I know, but I'm not sure right off how it relates to the 1000AT.

We have several LDG tuners being used in Emergency Operations Centers where there are significant noise sources inside the building. We were having significant problems with noise that would exceed S-9. While testing our equipment from one EOC on my bench for other reasons I happened to remove the power cable from the tuner while in receive mode with the tuner bypassed and noticed that the noise immediately dropped several S-Units. That should have had no effect on noise level.

On inspection of the tuner I noticed that there are separate ground areas on the board for the control circuits and RF circuits. These are tied together with jumpers that have a ferrite choke over them. This provides a DC connection between the ground planes but isolates the two sections for RF. I also noticed that the control section, which of course includes all of the relay coil connections is intermingled with the RF components and circuitry. The problem with this is that noise that will naturally be coupled (common-mode) onto the power and control lines to the tuner from local sources can then be coupled into the RF section components and traces due to their proximity.

We replaced the choked jumpers with straps to tie the two board sections together for RF as well as DC establishing a common ground plane for the entire tuner. This essentially eliminated the noise being coupled in from the power and control lines and attaching or removing the power cable no longer had any effect on noise level.

I've seen this configuration on a number of LDG tuners and frankly never understood the reasoning. I've also seen LDG tuners where the power input has no bypassing for noise near where it enters the chassis. Since your symptoms are exactly what would be expected with this problem I suspect your tuner suffers for the same reason. So, you might want to simply try disconnecting the power and control cables from your tuner while it's in bypass mode to see what the noise difference is in your receiver. If much of the noise goes away, take a look inside to see if it's build that way.

Well, that is what I was thinking, but I was afraid it was something I was doing wrong. I have never used an automatic antenna tuner before. This has me scared off.

If it wasn't for the trip next week, I would just send it in for repair. I have a simple manual tuner on the way from Gigaparts. Still looking at automatics, tried to order an MFJ-993B, but MFJ out of stock, and if I order from a dealer, and it doesn't work, they won't take it back.

The lure of an automatic for use in a car or airplane is great, but not sure the promise is going to work out.

Thanks Charles.

Bill,

We have never received an e-mail or message from you. Did you try the direct address listed on the web or in the manual? It does not say that phone support takes 5 days. It says that any support is usually less than 5 working days.

We have never said that if you open the tuner, you void the warranty.

Sounds like RF getting into the power supply ground to me. Depending on the supply used, a couple of snap on chokes on the DC power lead would probably fix it.

Hi, thanks for responding. Actually I got the link to this site off your website.

I went to the support page last Friday, and it said to use the form, which I did. I used a gmail address, that started with billnancy as the reply. I filled in the captcha stuff. The website says to email, and that usually takes less than 5 days. It doesn't say how long phone takes, but says phone is the "slowest method."

I must say, I ASSumed opening would void the warranty, most people say that. Really wanted to do that. I will now in hopes of spotting something simple.

I only have one larger snap choke, I got with a tarheel 2, which I can put on the power lead. I don't know how these things work, but since the relays are not clicking when the swr is changing, I must admit to not listening closely to another members thoughts on power supply filtering. I have never experienced this type of problem on manual tuners, so I didn't think that would work. I have the one choke, and I will install it.

I still don't understand, if the algorithm uses relays to switch in and out values of C and L, how does the swr move after the switching is complete. Is the power supply doing something else?

Because I was on such a time line, and felt the form on the web page was the required support method, and since I received no errors there, I felt impatient, therefore I called Mike at Gigaparts, who couldn't suggest much, but was sympathetic, and ordered a manual tuner. I still want an automatic tuner.

I am sorry if some website glitch caused you not to receive my email, I probably should have just sent regular email rather than use the webpage.

6046. Re: MFJ-993B tuner... was AT600PROII Continuously retunes

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2013-03-16 06:01:13 UTC
From: Ken
Topic: 6008 Message: 6046

The MFJ-993B is a nice tuner but heads up on the one common problem it and some similar models have.. The power switch will fail.. It is a very cheap poor quality switch. We have a thread going on this in another group. Mine never lasted a year. Some users reported changing the switch several times. When you contact MFJ and finally get a response, they sent you an envelope with several replacement switches.. no note, on comments.. just the switches. We've come to the conclusion it is best to not use the power switch, turn the power on/off with your station power bar. If the switch has failed, jumper the switch (bypass), if you don't want to opt in to the cycle of replacing switches and take the chance of causing other problem in the process. You have to remove the front control panel to get at the switch.

I was also disappointed to find that neither the analog or bar graph meters have a provision for indicating power in PEP watts.

My MFJ-993B is still on the sick list.. waiting a few weeks until the WX warms up a bit more. My work shop is in my big shed and takes too long to warm up in the winter.. hi.. My 2 LDG Z11Pro tuners are working fine and keeping me on the air. ..

6047. AT-200Pro weird response ?

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2013-03-17 02:21:01 UTC
From: nekmail@verizon.net
Topic: 6047 Message: 6047

I've just noticed that when I tune (most notable in the CW section of 40m)my multi-band dipole that the SWR bars will light up at 3.0 Over for a split second longer. When I tune the same frequency on my Butternut H69V it might ramp up to 1.3 and that is about it, but gets tuned to 1.1 ..

When I hit the tune button for the 2nd time it will do similar (ramp up over 3.0), but usually by the 3rd tune press it synches in without any 3.0/over display.

I've checked both antennas with my RigExpert AA-54 and all is in very good shape/tuning there.

I'm wondering if there might be a sticky relay that is occasionally giving fits in the AT-200Pro Autotuner ??

Any thoughts from the group?

Bill, I've sent you a couple of emails to see if I can buy your AT600PROII. I do not know if you have gotten my emails or not. I wasn't sure if the email address you have on this site is correct or not.

Dwayne,

I opened the unit, did not see anything obvious. I did not raise the circuit board, just looked for anything burnt of loose.

I did put the snap choke on the power supply lead(s). No change. I changed from a Jetstream 45a supply running everything, to a pair of Kenwood KPS15's, no change. If you can, please suggest something else.

Thanks,
Bill

I'm sorry, yes I received them. I was just about to move that direction, and then Dwayne suggested some things. Nothing seems to work so far, I need to solve it soon, or I will be selling it for sure. Of course I hate to lose over 100 bucks on the deal, but hassle factor is high, and I might yet go that route.

I tried a couple of other things, I used the Jetstream for the radio, and then one of the Kenwood supplies for the tuner, with the snap choke. That didn't work either.

Everything works fine at 10 or 20 watts, but when I turn the power up to 200, the swr starts changing. At 100w, it takes longer before it starts changing.

There is probably stray RF in the shack that is sending spirous currents down the coax toward the tuner. Try making a coaxial balun/choke out of RG-58 and insert it between the tuner and the antenna inside of the radio room. Take a 10" long piece of 1" pvc and tightly wrap 29 turns of the coax around the pvc. I did this with my Z-11Pro II and it immediately fixed the problem.

Good luck,

Mike, NA5SS

Bill;

Let me throw an "oar" into this water.

Since the "erratic behaviour" you describe is power dependent, it really, truly, almost absolutely seems to me that you are experiencing RF feedback from somewhere. To me this means that you have RF on the outside of your coax, which is getting into the innards of your tuner. The RF can come from faults in the coax, poor grounding, stray pickup from your antenna to the AC wiring in your house, or coming through the control cables from your rig to the tuner (if that is needed for operation of the AT-600).

Have you tried your tuner in someone else's hamshack where the other person successfully runs 200 watts or more with an identical or similar tuner? That's the only "conclusive" way to be sure that your tuner is functioning correctly or that it has an internal defect.

I personally know that with the cheep jumpers made from poor quality RG-58 and "almost obviously inferior connectors" which I purchased from Rat Shack, that running 90 to 100 watts is sometimes problematical with my Z-100, but it works flawlessly when I run 5 to 10 watts. Since I generally run 5 watts or less, I haven't invested in good quality jumpers. However, a friend who runs 1.5 KW tells me that he needs to have >130 dB isolation in his shack to prevent weird RF problems, so he uses the very highest quality coax and fittings, and from the amplifiers to the ATU's and thence to the antennae he uses type "N" fittings.

I don't recall exactly where I saw a comparison of "standard, run of the mill" coax and connectors vs "contest grade" fittings, but the differences were surprising to me, since I had never considered the need for 130+ dB isolation between the inside of coax and the outside. Some of the "garden variety" jumper cables provided considerably less that 100 dB isolation. Perhaps someone here in this forum can provide the reference. It "probably" was in either the National Contest Journal because the article was about multi-multi contest stations, and "probably" was in the past two years.

As I had posted previously under "And other weirdness"

I run 100 watts with a Z100 Pro II. It was working just fine.
It developed an issue where it would constantly want to retune.

So I thought about "What changed here? What wasn't here when it was working correctly?"

The thing that changed was a HP all-in-one copier I bought used. I put a choke on the USB cable at the PC side and the problem went away.

Conclusion.... RF can get in anywhere and cause a problem, it's not JUST the power lead to the tuner.

Jeff is correct. One of the items discussed in the YCCC document and common mode currents was that you need some hi impedance at both ends of the feedline and power leads.

Stray RF is a pain to sort out, but there are many excellent solutions that have described here.

There is no guarantee that your problem will go away with a different make of tuner. While it might seem to disappear, it may be a different trade off.

Good luck

And it can be in some of the stranger places.

When I first put my station back on the air 2 years ago, I would add equipment and see what happened.
One of the stranger items was adding the "ground buss" behind and to the right of the station.
3/4" copper pipe with brass 10-32 screws soldered in every 18" to tie the equipment together.
Just setting the pipe behind the station upset things. After I tied everyone to the pipe it calmed down until the next iteration of strangeness.
Adding a PC to the mix set off an entire new round of "now what?"
Keying the transmitter would temporarily freeze the mouse. 4-5 times until the PC locked up entirely. A ferrite snap-around choke on the mouse solved that.

Short answer: "How many cables do you have connecting everything together? Each one of them is liable to be a problem."

It works both ways too. Back at my radio shop in Los Angeles I was plagued with noise at 25 KHz intervals on every HF radio I listened to.
When I moved to Texas it followed me. Again, "What changed and what is the same?" It turned out to be the Panasonic PBX for the phones.

Hello BILL,

IN an effort to solve your issue, this suggestion is very very important for you to do!
So far I have not seen a post that you tried this test? Suggested by
DAVE 2E0DMB

Also are you a HAM? I have not seen your call sign posted in this forum? Please post you Call Sign and location, maybe a Ham nearby can assist you with your issue!!

hi have you tested the tuner with a 50ohm load to see if it still retunes,
i did have a mfj tuner that did this and it was a dry solder joint on one of the inductors
THANKS DAVE 2E0DMB

All:

I think it's important to listen to the symptoms being reported. The key symptom, assuming he is reporting it as it really happens, is that the SWR ramps up as long as the transmitter is keyed. Higher power causes that to happen faster. I also believe he said the SWR is showing increasing on the meter on the radio. If not, that would be a critical piece of information.

This is not a symptom of stray RF. It's a symptom of something heating. Since this doesn't happen when the tuner is bypassed, it's very likely to be a problem inside the tuner. There is the odd chance that he's been testing it with an antenna that requires an odd tuning solution that's stressing a particular part of the tuner, but that didn't seem to be the case from what he was describing.

Since it's possible it's a particular part, path or relay, it may behave fine on other frequencies or with other loads, but that may not mean the tuner is OK.

In this case, if there's no visible indication of heating at any of the PC board connections or components, the thing to do would be to measure contact resistance through the relay contacts, but NO and NC connections. That means you need to get in there an cause each relay to pull in to test all the contacts.

Again, I don't see how the symptoms are related to stray RF. Simply throwing suggestions at a problem randomly is not really helpful.

Hi Chuck

It could be an intermittent in the antenna or even the balun. A crack in the balun (if there is one), may contribute. Do we even know that the antenna is or what frequencies it happens at? 40M tends to be the worse.

I'm not convinced this is not an RF as I have seen the same symptoms in my station with a Windom and AT1000Pro even at the 100 watt level.

We also don't have a full topology of the system setup, so that could be a contributing factor. Grounds, ground straps, ground resistance, inferior jumper cables, etc.

Sadly, we likely will never know the real cause.

Mike:

Again, we have to follow the symptoms reported. The problem does not exist with the tuner bypassed. This seems to exclude problems with the antenna. Stray RF issues happen more erratically and do not "ramp up" so to speak.

It would be nice to actually be there to see first hand what's going on. Short of that we have to try to help the person by what they're reporting.

6065. Re: AT600PROII Continuously retunes

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2013-03-18 23:18:43 UTC
From: Jonathan Helis KB5IAV
Topic: 6008 Message: 6065

I've had a problem with my Z11 Pre constantly retuning itself. I'd get the SWR down to 1:1 and sometimes during a QSO, it would try to retune itself. In fact, if I keyed up my 2meter handheld, which is not conncted to the tuner, it would sometimes retune.

I put the tuner in manual mode, so it only tunes when I push the button. That was the only workaround I could find that would solve the problem.

I have transmitted to much power into my AT-100 Pro II. There is a resistor that is completely destroyed. I need to know the value and power rating if anyone can help. It is on the board next to the coil labeled T1 that the lead from the antenna input connector passes through. It does not have a number on the board that I can see. It might have been under the resistor but that is no longer readable. The board is version AT-100 Pro II V1.1

Any help would be appreciated. Thanks << John

John,

It's a 150 ohm, 1/2 watt, non-inductive resistor.

Ah,

His ground is not a ground, but a radiator. I bet it is about a 1/4 wave on 40m.

I operated out of a 2nd floor before, and I had to NOT have a ground to solve some problems.

MFJ used to have a device that was used to tune your ground bus.

Dwayne,

What's interesting is that I was able to interface my DX-SR8T to an Icom AH-2 remote autotuner. It worked fine. Shouldn't any AH-x compatible tuner work the same?

6072. LDG Customer Service

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2013-03-20 22:07:39 UTC
From: kdwb6343
Topic: 738 Message: 6072

Just wanted to express my appreciation for the Excellent customer service provided by LDG recently.

I bought a new AT-1000Pro II a couple of weeks ago and had a little difficulty getting it to work with my station setup. Read the manual, watched the videos . . . still not working as I expected it to.

Dwayne jumped in and (via email) walked me through all the setup and connection procedures, asked questions about my specific station, and made some recommendations. That solved the problems for the most part, but Dwayne was still not quite happy with my situation. He decided I needed an upgrade to a later version controller chip. He said it would go out early the following week and that I should expect it a few days after that.

Instead, Two days later, it showed up in my mailbox. I removed the tuner's cover, put in the new chip, and re-installed the tuner. From the first button push on, everything worked perfectly.

I've seen poor or uncaring customer service from companies and really don't understand that. LDG wasn't satisfied with my tuner working mostly right. Dwayne kept at it until we had it working exactly right.

LDG,both product and service-wise, is at the top of the heap.

Many Thanks to a great company!

73-

Tune the L down until it won't go down any further.

Tune the C down until it won't go down any further.

Now you're in bypass mode :) Of course if you're in an automatic tuning mode the tuner will try to re-tune if the SWR is unacceptable when you try to transmit.

I wasnt blaming LDG, I was just asking. I am powering it from the same power supply that runs my Icom 746. It ran the MFJ auto tuner (993B) with zilch noise. I took the LDG out and installed the MFJ for now. And have the amplifier out of the circuit for now. The amp was never plugged in either. It wasnt consistent, but when it did make noise, it would do it as long as it was powered on. There was times it didnt make noise. I am going to move it further away from my radio, but still easy to reach/operate. I think I will run the MFJ between the radio and amp, then run the LDG AT 1000 Pro II after the amp. I will see how that works. And report back.

Rick

I am interested in communicating with others who use the IC 718 and LDG auto-tuner with an attic G5Rv Jr (HOA, apartment, or condo). Who might they be?

6086. How to store freq data

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2013-03-23 02:35:24 UTC
From: V
Topic: 6086 Message: 6086

Storing data? Manual says Func/Store. Another source says Hold down Func and press Store. I have done both - many times. I question if anything is being stored. Why do I think this? Move to new band. While in auto mode press Tune button and it finds a number at or below my VSWR threshold. Then I trim it with either Cup/dn or Lup/dn to improve the VSWR. Now with Func/Store (using both methods listed here) info should be stored. Move to different band. Go through a similar procedure. Now move back to previous band and key radio but the VSWR does NOT return to my last best settings. It is within my VSWR threshold, however.

Why is it not resting at the best known VSWR for that band?

If my words are unclear, please ask me to clarify.

Vern

Topic: 6088 Message: 6088

Hi,
When i use the tuner with my radio the tuner behaves itself swr low....as soon as i switch in the linear 150 watts the tuner keeps hunting .....and finally gives up......i have tried my other radio ft897d at 100 watts into tuner ..no problem swr low.....could it be the amplifier has a dirty output causing the at200 pro to keep searching ??
Funnily if i then use my other LDG autotuner Z11PRO11 IT ACCEPTS THE AMPLIFIER 150 watts output with no problem .....is the AT-200PRO 11 JUST MORE FUSSY ??????

Try placing the tuner in semi-automatic mode. That is what LDG recommends
for use with an amplifier.

6096. LDG Z-817 Tune-up Mode Switching Problem

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2013-03-24 13:08:25 UTC
From: Alan
Topic: 6096 Message: 6096

I wonder if anyone can offer me some advice with the following problem.

I have a Z-817 auto-tuner and I'm using it with a Yaesu FT817 ND, connected using the supplied CAT cable. The tuner works as described, with one exception...

If the dial frequency is changed, even by the smallest amount, the next tune cycle fails because the transceiver fails to switch from the current mode to the tune-up mode (i.e. Packet). This happens in both memory tune and full tune cycles. Having failed once, subsequent tune cycles work fine, with the transceiver switching to Packet mode. However, once the frequency is altered the problem re-occurs.

The FT817 is set up as per the Z-817 manual. I have replaced the batteries and tried a substitute CAT interface cable, but to no avail. I have contacted LDG and am currently awaiting a reply.

I wonder if anyone else has come across this particular problem. Any advice would be received with interest.

Thank you

A D Grove, G8BJG

6097. AT-600pro troubleshooting

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2013-03-24 16:44:45 UTC
From: rick
Topic: 6097 Message: 6097

I bought my tuner last May and I have noticed that it is starting to be difficult to get a descent SWR (less than 1.5) when tuning my radio to the tuner at low power. Once I apply power via my solid state amp (500 watts or less), the SWR is around 2 or even more and my amp tries to kick off. It seems it is not doing the job like it used too when it would give a 1:1 match almost 100% time even at nearly 600 watts. Without the tuner, my SWR is around 2 to 2.4. I've tried using the up and down C and L buttons on the unit but it has not helped my situation. I do not think there is a way to reset the 600 pro?
Any ideas would be helpful.

Thx...Rick KF4VGV

6102. NEW Kenwood radio interface for LDG AT600ProII and AT1000ProII

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2013-03-27 00:25:37 UTC
From: Stefan
Topic: 6102 Message: 6102

Build a Kenwood <> LDG tuner radio interface featuring:

*** Radio Interface
Tune button on transceiver can be used to start tune or bypass tuner.
Repeated tune in 3sec will start Full tune.
CAT command can be used to start tune or bypass from PC.
Compatible with TS-2000, TS-480, TS-590 or any rig capable of controlling Kenwood AT-300 tuner.

*** Remote Control Panel (optional)
Using just 2 LED's and a push button to change antenna ports on remotely installed tuner.

*** Computer Control (optional)
Connect to PC LPT port to switch between antenna ports or bypass tuner. Ham Radio Deluxe can be configured to automatically change antenna when changing bands.

*** Automatic Power Amplifier Control
Safely switch OFF the Power Amplifier during tuning, changing antenna port or bypass operations.

My 1000ProII will go to bypass if there is no tuning required.

hi all,

I recently purchased 100pro II to work with my 817ND.

In fully auto mode after tuning on particular frequency the bypass light is turning ON. Is this normal???

Appreciate experts ideas on this.

May be my one does the same. After fully tuned on a frequency it goes to bypass mode.

6112. z817H tuner

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2013-03-31 19:46:52 UTC
From: radiohenry
Topic: 6112 Message: 6112

Hi,
I notice that even though my z817h green LED will blink for one second on all bands when tuning (which should indicate a very low SWR), unexpectedly both a SWR meter and the FT817 lcd SW bars show a far higher SWR when I tx a CW carrier at 5 W. Could it be a symptom that the tuner is damaged? I have been running up to 60 W for long duty cycles recently, I wonder if I may have overloaded the tuner.
Thanks in advance for your comments
73 Enrico

6116. AT-100 Pro II and Long Wire

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2013-04-02 18:31:32 UTC
From: Walter Beck
Topic: 6116 Message: 6116

I have a Kenwood TS-440 SAT that I have dedicated to a long wire antenna. The wire is roughly 100 ft long and 20 ft above ground. I have a 6 ft copper clad rod driven into the ground as my ground. All the equipment in my shack is grounded including the tuner and the balun.

The problem I am having is simple but I am not sure why. The tuner will not find a match on bands below 14 MHz.

I have tried with no balun, a current balun and a voltage balun. The baluns are LDG baluns.

If anyone has any suggestions, I would really appreciate them. I was thinking that it might just be that the long wire is not long enough but thought that the impedance matching range of the tuner with balun would be able to handle that.

Thanks in advance.

Walt:

The tuner in the TS-440SAT may not be able to tune your long-wire antenna. It has a limited range so tuning a random length antenna may not work on some bands. You may also have other issues with your antenna installation. For example, you're apparently relying on a single ground stake for the "ground". All long-wire antennas have another side to the, which is what's connected to the other termination of the coax (shield). Your "ground" may not really be that other side of the antenna on some frequencies. The rest of your antenna could be your transmission line and anything connected to it. In other-words, there's some considerable variables here.

To use a long-wire antenna with your 440 you will probably need a different antenna tuner, preferably placed at the feed-point for some bands.

I have used similar arrangements with LDG tuners. Try a counterpoise or radials, some series inductance on the output or even some series capacitance.

I apologize for not being clear. Evidently putting the name and model of the LDG tuner I am using with my 440 was not enough to indicate that my question is directed at it and not the tuner in the 440.

Now that I have tried to clear that up, any suggestions as to why the LDG AT-100 Pro II that I am trying to use with the Kenwood 440 will not tune up on the bands below 14 MHz?

By the way, I bought the LDG AT-100 Pro II because I knew that the Kenwood TS-440 internal tuner would not handle the long wire.

Any suggestions are much appreciated.

OK, but much of my post still stands. Since the "ground", "counterpoise", or whatever you'd like to call it in your installation is not well defined, there's no way to know what the installation looks like to the tuner at various frequencies. It could well be that the tuning solutions required for some bands are outside the range of even the LDG tuner.

Is the tuner in the TS-440 disabled? If not, the LDG will be "fighting"
the internal tuner.

I've usedsimilar antennae way back in the 50's, and it wasn't hard to
get a match with an L-Match.

Personally I would go (and have) with a AT100. The YT100 can only be used with the 8x7 while the AT100 can be used with any radio in the auto mode. Building a cable for using the tune button on the tuner is trivial. Main down side is the AT100 will require a separate cable for power but that can also be pulled from one of the radio connectors.

Didn't he imply with his message subject that he was using an AT-100 Pro tuner, not just the tuner in the rig?

I suspect his problems arise due to poor grounding. A single 6 ft ground rod isn't enough of a good RF ground for a 100 ft end-fed wire antenna.

Thanks Chuck,

I will work on my ground system and see if that improves the situation at my QTH.

I had been using an AEA AT-300 manual tuner in the same configuration as I am trying to use the LDG AT-100. It has allowed me to tune all bands with the Kenwood TS-440. My bad assumption was that if an old technology manual tuner worked then a newer technology LDG tuner would also work and automate the tuning task.

Live and learn. Since I have invested money in the LDG product, it would be worth my while to get it working. First is to improve the grounding as you suggest and second might be to extend the length of the long wire.

Thanks again

Thanks Hank.

Actually, I tried with the internal tuner in circuit and out of circuit with the LDG. Different results but better without it in circuit. I am going to work on my grounding to see if that is deficient.

I have been using an AEA AT-300 manual tuner in the same configuration that I am trying to use the LDG AT-100 and the AEA has tuned up the TS-440 on all bands. Bad assumption on my part that if old technology worked the newer technology would work better.

Thanks again

Manual tuners in general have a wider tuning range than auto tuners.

This whole thread is a puzzzle. He has described a system with no balances element, yet claims he uses a Balun (BAlanced to UNbalanced); why? His "Long Wire" is pretty short, and he has an inadequate ground.
What help can he be given?

Have you tried any common mode chokes?

Bill,
Actually, I have received quite a bit of information that will help resolve my problem. As far as why I am using a Balun, the instructions and recommendations that come with the AT-100 and on the LDG web site state that a Balun should be used when connecting to a long, or in my case according to you, a short wire antenna.
I have gotten the message that my ground system is not adequate. I am working on improvements by adding additional grounds over a wider area. I am a bit limited because of the septic system location in relationship to the house. I am also looking at what it will take to lay a network of radials keeping in mind the septic system.
For grins, I have an old MFJ Artificial Ground that I used when operating my station from a second floor QTH. I may roll that out and run some experiments with it to see what happens.
Worse case, I go back to my manual tuner and sell the AT-100 on eBay.
Thanks for your comments.

Walt.

The only thing a poor ground will do is "burn" some RF in the ground system, rather than radiating it. For years I end fed a wire of about 100 feet, with a single ground steak, probably no longer than 3 or 4 feet in "somewhat mediocre ground" and worked 40 states with one crystal at 3721.9 KHz. This was long before the daze of computers, so RF floating around the shack only would give me an RF burn if it was of any great magnitude, which it wasn't.

And, I often run my LDG Z-100 tuner with a 33' length of wire and a 33' single counterpoise, with no ground steak at all when I'm out in the field, on 40 and 20. Yes, for all those "purists" on this reflector, I know that on 20 the 33' counterpoise means the "chassis" ground is at a high impedance part of the setup./ But it typically doesn't matter. If I ever did have a problem I'd double back the 33' length on the counterpoise and it would be a 1/4 wavelength on 20 meters which should take care of any "floating RF."

FWIW, my current "shack" is on the 2nd story, and I have no "ground" attached to the rig's chassis. I feed a dipole with 400 ohm (nominal) window line, and have a LDG balun (either 4/1 voltage balun or 1/1 current balun) whichever works best for the band I'm using) between the balanced line and the LDG-Z100 tuner. Maybe I'm lucky, but I can match all bands 80 through 10 with the tuner, and there's no RF floating around. The conventional wisdom says one NEEDS a physical ground, so, I guess I'm violating some law of physics and/or electrical engineering. It works with 5 watts or less, or even in those rare occasions where I crank the rig up to 100 watts.

I'd say that, in your case there must be some RF floating around on the outside of your coax caused by proximity to the longwire antenna. A choke or what folks now call an "un-Un" just a few toroids large enough to fit over the coax at the tuner and at the antenna, to provide a high impedance for any RF which is picked up in the field of the antenna before can reach the rig. And, it's a good idea to ground the outside of the coax with whatever ground available (even a 6' ground steak) at both the antenna side and as close to where it enters the shack as possible.

Using a MFJ artificial ground might solve your problem. We've used one of those @ Field day several times in the past to "tame" a "hot chassis" on a rig, when we're too lazy to figure out from when the RF is coming, because we have a balanced wire feeder which should not generate RF on the chassis.

There's nothing wrong with installing as large of a counterpoise system
near ground level, but I'd guess, with somewhere between 0 and 99.44%
certainty that this is NOT causing your problem.

Hope this helps.

Walt--
Don't ignore the possibilities in that Septic system. The soil near the field lines is always moist, and the liquid should be somewhat conductive and changes little with season. If you know the location of the field lines, you might be able to offset ground rods to take advantage.
I have a large stand of Timber Bamboo (4-5" Dia, around 50' tall) that is helped by such a field. The only problem with the Bamboo is that it is moving toward my Tower.
Another factor-- I have an acquaintance who had to Zig-Zag his 160M long wire from tree to tree, in many directions to get enough length. I modeled it once, and it looks weird, but it worked.
I think LDG may have meant "Common Mode Choke", when they wrote "Balun", like many other people do.
Good luck--Bill--W4BSG

Hank,

Thanks for the information. My station and antenna grounds have worked with my AEA AT-300 tuner and both Yaesu and Kenwood rigs on HF, VHF and UHF.

I am still planning on going over my current ground system to see if it can be improved. One thing I have learned over the last 20+ year of operating is that every station configuration at every QTH has completely different characteristics and what works at one to establish optimal conditions at one can create issues at another.

I ran for several years from a second story QTH with no physical ground, no tuner into a G5RV Jr and qualified for several awards.

I can appreciate your estimate of confidence as mine generally falls within the same range. :-)

Bill.

Good point about the septic system. I have a feed point to the tanks just a few feet from my ground point. I think I will stick another copper rod on the other side and see how that works. I also am fairly close to the under the house access and its always fairly damp under there. I may stick another rod or two there also.

Like I said, if you go to the LDG site you will see they specifically describe the use of current mode (RBA-1:1) balun or voltage mode (RBA-4:1) balun. To quote the instruction "manual", "Your LDG balun allows you to connect longwires and antennas fed with ladder line to your LDG tuner." Nowhere on their site or any documentation talks about the use of a common-mode choke.

That does not mean that I may not require the use of a common-mode choke and, since they are easy to construct, I am adding that to the list of things to try.

I might even try adding several to the current wire.

Thanks for your suggestions. They give me something to play with on those days when I do not have a list of "honey-dos" from the XYL, N7TIL.

Walt--
I didn't know you used Ladder Line. How is it connected at each end? It is balanced, and usually is connected to unbalanced (Coax) at the rig or tuner end with a Balun. At the antenna end, how is it fed? is that where the LDG Balun is?
The beauty of Ladder line is not that it is easy to match, but that it is low-loss when miss-matched.

This weekend, I worked the Texas State Parks On The Air contest and was quite successful with my FT-817, the little LDG 817 tuner and an inverted V using 86 feet of wire with a 17 foot counterpoise parallel with the antenna. Here is information on this antenna:

http://home.frognet.net/~mcfadden/wd8rif/field-antennas.htm

6138. Z11Pro II not bypassing

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2013-04-09 07:15:13 UTC
From: m0lmk
Topic: 6138 Message: 6138

Hi group.

I have a Z11Pro II that just won't take a break. According to the manual, pressing the tune button once will make the LED's flash 3 times and put the tuner in bypass mode.

However, when I do this, the tuner still seems to click relays and tune the antenna. I did think that maybe the clicking is just the tuner resetting the relays to "bypass" but it will also do the same if I change band.

I have an FT-857 (10W) connected to a SWR bridge, then the tuner and an Alpha Delta DX-CC antenna.

The Alpha Delta DX-CC is resonant on 80, 40, 20, 15 and 10 meters so I would expect that the tuner would just sit quietly and not do anything.

As another test, I also put the tuner into bypass and called on 17m. I expected to see a high SWR but the tuner jumped in and started to tune.

Am I doing somthing wrong?

Thanks,

Matt

A quick push on the tune button temporarily places the tuner in bypass
so you can spin around looking for signals. To keep it in bypass you
will need to set the tuner for semi-auto mode (Func C-Dwn) then it won't
tune unless you press the tune button with RF present.

Don't be surprised if you need a tuner on 15 meter with the DXCC. It
uses the 3rd harmonic of 40 so it may not be much better than a 3:1 swr
where you are interested in working. Depending on the vintage of your
857 it may start folding power back at 1.5-1.7:1 swr.

Perfect!

Thanks Leonard. There was me thinking that "bypass" meant "bypass"!

Just tried it and it's now working as expected.

Bill,
I do not use ladder line. I can see where you got that idea. The sentence I quoted, "Your LDG balun allows you to connect longwires and antennas fed with ladder line to your LDG tuner.", needs to be parsed correctly. :-)

Take a big pause between the word "longwires" and the phrase, "antennas fed with ladder line". They are meant as separate entities. If you download or look at the manual for the LDG Baluns on the web site, on page 4, you will see their illustration for connecting a longwire to their tuner through a balun.

The longwire is connected directly to the antenna terminal on the balun and a ground rod is connected directly to the ground terminal on the balun. The coax connection is then wired to the tuner.

That is exactly the configuration I have been running with, as I have said, with no balun, a voltage balun and a current balun without getting the AT-100 Pro II below 20m. The no balun configuration is not recommended by LDG but it was easy to rig up, so I tried it.

Thanks again for all your suggestions.

Walt--
I see the figure on page 4 of the LDG manual. From their note, the expect your 100' wire to be OK above about 80M.
How high is the Balun above ground?

Bill,

The Balun is located at the radio since that is where the long wire is being fed - out of the Kenwood, to the Balun, from the Balun to the longwire and ground.

Do you think it would be better if I ran a coax long enough to fed the Balun and the end of the longwire outside the shack and higher in the air? That would roughly but the Balun 20 ft above ground.

Thanks again. By the way, I am going to purchase several more ground rods this weekend and start creating a better grounding system.

Greeting to the group...

I have a problem with my new 600 Pro II that you folks may help me with.

I have a 200 Pro II that I use with a Kenwood TS-940 and a 41 foot vertical which works great and I could not ask for a better Auto tuner. Tunes fast and a low SWR on both the Bar Graph and a second SWR meter.

I purchased a 600 Pro II to use on the same setup with a amplifier in the future. It tunes OK on 40, 15 and 17 but not as low a SWR as the 200 Pro II. But it will not lock up on 20 and shows a SWR above 1:7 or above 2:0. I TX LDG but did not get my problem solved to my satisfaction. They suggested setting the SWR threshold higher than 1.7. I set it to 2.0 and higher with no better results. I switch back to my 200 Pro II and its 1.3 or better right away.

Any ideas? Thanks in advance.

Walt-- (a delayed answer)
Thanks for clearing that up. I see nothing out of line with that, except that a significant part of the wire is not higher. Just for curiosity-- how do you feed the wire to the outside?
About putting the Balun up at the wire, I see one potential question; assuming Coax feed, this makes the ground lead a part of a doublet, but grounded at the end. I will need to think some more about this. The lower end of the Coax shield and the ground wire are both at ground potential, but any location above that, the ground wire has a different current, because of radiation. Since this is the situation shown in the manual, maybe LDG has an answer.

Bill,

I left out a very important bit of info in the first paragraph. It should read, "out of the Kenwood, to the LDG AT-100, then to the Balun, then to the longwire and ground.

Sorry.

Walt--
Don't worry; That was my understanding, based on one of your earlier posts. You mentioned that the Balun was connected by Coax from either the Tuner or the Kenwood.
Another "curiosity" question; I have seen your area on a map (QRZ), and from above, but-- what is your altitude? I am at 1620 ft ASL, 1000 Ft above the (local) Tennessee river, on the highest point in several miles.

6152. LDG 100W tuners and Kenwood TS-590S

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2013-04-12 17:10:03 UTC
From: mcyman
Topic: 6152 Message: 6152

Hi All,
I have a Kenwood 590 and an IT-100 tuner, with Icom cable.
And was thinking about using the It-100 with my 590.

I was wondering if anyone has interfaced any LDG tuners with the 590?
My owners manual shows the 590 can be used with the Kenwood AT-300, as the 590 has a 6 pin Molex type connector on the rear chassis tor the AT 300.
The 590 AT connector has 13.8vdc,ground, a TS (Tune Start) and a TT control in/out connection.
I read somewhere that some of the lDG tuners can be used with Kenwood radios that can interface with the Kenwood AT-300.

Thanks rob N8RT

You need the now discontinued Kenwood OTT module. Not even sure that
will work with the IT100 but should work with the generic LDG tuners.

You can use the new AT-600ProII and AT-1000ProII with this interface.
Look at http://af6sa.com/projects/UTI.html

Hi Rob,

Unfortunately, you have the wrong tuner to use with the TS-590. The IT-100 is made specifically for use with Icom radios. The simplest and maybe even cheaper solution in the long run is to sell the IT-100 and replace it with a LDG tuner that will do the job with no hassle or need for an interface connection.

There are several LDG tuners that will work but from my experience I prefer the LDG Z11PRO. With this tuner no interface is required as the tuner works with RF sensing and the TS-590 has the provision to program a PF button to preform the tune function. I use PF A set for tuning (menu item 79 - set to 204 - TX Tune - Page 56 in manual). All I have to do is press PF A, the radio switches to CW and puts out a 10 watt carrier, the Z11PRO senses the RF and tunes. Nothing to it.. works great every time. I use 2 Z11PRO tuners with my TS-590 and have never had a single problem!

From: mcyman
Topic: 6152 Message: 6156

I would like to thank all that responded to the Kenwood 590S, message that I posted.

Thanks to AD7AS, AF6SA, VE5KC and others.

I managed to obtain a LDG Z11Pro, and followed VE5KC info below, and Bingo , the Z11 and the 590 are working together very happily.
One press of the Kenwood PFA button and the tuner zero's out any SWR.

Many thanks Ken VE5KC for the info.

By the way, I did discover another great feature of the 590S, while testing tuners and antennas!

My antenna system consists of, 10ft of Rg58x,going into a 4:1 Balun, than, roughly another 30 ft of #28 wire, out of the balun, the other side of the balun is connected to a ground rod.
The Z11 was able to tune 80 to 6 meters perfectly.

I live in an HOA Antenna restricted community. And had to put up a Stealthy antenna, so far so good!

I than decided to see if the 590 tuner would be able to tune out the antenna SWR! So disconnected the Z11, and connected the antenna coax directly to the 590.
Much to my surprise I found that the 590 could also tune out the antenna SWR ,on most bands except 40, the 590 zeroed out the SWR on all of these Frequencies,
3.5,10.1,14.2,18.13,21.3,24.9, 28.3, and 50.1 Mhz. That is pretty amazing for any Transceiver's INTERNAL antenna tuner!

Most other Transceivers that I have owned, would never have tuned the antenna system that I have!

However, for some reason the 590 tuner could not get the 40 Meter band to tune out, the antenna's SWR ?

In the future I will try extending the Coax from the radio, I think that may fix the issue!

Hi Rob,

Glad it worked out for you. I've had a couple other LDG tuners and found the Z11Pro was able to tune a much wider SWR range. The Z11Pro even did a good job of loading up the eave-troughs as a temp measure. I have a MFJ-993B that is also very forgiving with my antenna setups but is out of action due to MFJ using a cheap crap power switch. A common problem for most all users of this and some other models, the switches seldom last a year. It is getting warmer now so soon I will get it on the work bench, in my shed and solve the problem.

I also found the TS-590 tuner worked fairly good on my poor antenna. The problem for me is that it was no always consistent, I could not depend on it to always work the same. Sometimes it wouldn't even try to tune. The Z11Pro setup has proven to work reliably for me for years. Before I bought the TS-590, I uses the Z11Pro with several Icom rigs (with tuner cable). I'm glad I bought a tuner that was not tied to a particular radio brand. That made it easy to switch to the TS-590.

I also have to live with antenna restrictions, very limited space. I live in a seniors housing unit with a small yard. I get a way with more than many others. I can not attach anything to the house and even got a lot of hassle over running my coax into the building.

Hi Ken, Ok on your Antenna restrictions as well. And I am sure you will have not have any trouble repairing the 993 switch.

I did try my 590 on several bands and it always tuned very quickly, and I did not have to fiddle with the AT button more that once! My 590 is about 6 months old ,and has version 1.07 firmware update;

I was surprised to read in the Z11 owners manual that the Z11Pro has 8,000 memories, that is amazing. And it is Keeper!

Ken, I wanted to mention to you that you might want to consider trying RemoteHams.com , Just download the Client software you can ask permission to transmit after uploading a copy of your license.

When my QTH was in a different location, I had REMOTEHAMS Server up and running, I Focused on allowing permission for transmitting, for hams with antenna restrictions.

Anyway just may be another way to enjoy ham radio!
All one needs is a Computer on the internet, running XP or win7/8.

By the way I was able to get the Dedicated IT-100 up and running by supplying DC Power to the 4 pin Molex connector, and setting the 590 manually to 10 Watts , and it worked OK as well.

But your right , a non dedicated tuner allows more flexibility.
Glad you led me to the Z11 Pro
Enjoy the Day.

From: gregoryd99
Topic: 6159 Message: 6159

Does anyone know how much current the YT-100 draws on the 857D CAT port 13.8v line? I blew the surface-mount 3amp fuse on the Main board and now VERY nervous after replacing it and getting the YT working again.

6160. Re: YT 100 trouble

Topic: 5397 Message: 6160

PS: You can check the 13.8v line on the CATA port to see if the voltage is there. That's how I found out I had blown the fuse.

Mine exhibited the same symptoms the 2nd time I connected it to my 857D. I diagnosed it had taken out the 3amp fuse in the radio. I replaced the fuse (this is a very tiny surface-mount part) and everything is working normal again. I'm not sure why or how this happend, but make sure you connect everything up and THEN turn the radio on. Also, make sure the ATAS menu is set OFF.

FYI, for those following this thread. LDG says the YT-100 draws a max of 300ma on tune, 7ma on standby.

6163. Z-11Pro Clone

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2013-04-28 22:23:59 UTC
From: Dwayne
Topic: 6163 Message: 6163

Just in case no one has seen it on e-bay. There is a company in China making an almost identical clone of the Z-11ProII

Here is the e-bay listing:

http://www.ebay.com/itm/50M-120W-SW-short-wave-Automatic-Antenna-Turner-Ham-Radio-/230954034187?pt=LH_DefaultDomain_0&hash=item35c5eee40b

Hard to believe that they copied it and still charging $20 more. We'll see more of these as time goes by.

Dwayne Kincaid

Unreal! I wonder if they copied the code or even how they would do that. As the saying goes: imitation is the sincerest form of flattery.

Hi Folks,

The US and China does not have a reciprocal patent agreement, so there cannot be an infringement. It would be more likely a copyright issue, but since they have no stores in the US, that is also unenforceable.

Thanks for the concern though,

That is the case in a lot of countries. I had a patent that got
accepted in Korea but the US didn't accept it. Good for a chuckle.

Complain to eBay? That's pretty funny. There a thousands of Chinese products on eBay every day.
And why are they there? Certainly not because they love to lose money on auction fees because nobody buys the products.

Yes, the Chinese tuner does look like an LDG Z11 ProII. Doesn't mean it _is_ one though. And be honest about it, if they were selling for $49, you guys would be sucking them up.

Armchair lawyers and engineers. Always good for a laugh. You're an embarrassment to the fraternity.

6180. NEW! Kenwood interface for ProII Tuners

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2013-05-01 21:43:30 UTC
From: Stefan
Topic: 6180 Message: 6180

Features:

Radio Interface
Tune button on the transceiver can be used to start tuning or bypass the tuner.

Remote Control Panel (optional)
Using just 2 LED's and a push button to change antenna ports on remotely installed tuner.

Computer Control (optional)
Connect to PC LPT port to switch between antenna ports or bypass the tuner.
Ham Radio Deluxe can be configured to automatically change antenna when changing bands.

Automatic Power Amplifier Control
Safely switch OFF the Power Amplifier during tuning, changing antenna ports or bypass operations.

More info at http://www.af6sa.com/projects/UTI.html

Hi Folks,

Thanks for all of the support. Any way you look at it, this is part of the business. We look at ourselves as innovators in this hobby, so almost all of our products are unique in some fashion and will inevitably be used by someone else.

We can't go around suing everyone that copies the stuff that we do. If that were the case, the list of lawsuits would be very long and we wouldn't have time to build new products for you.

Just off the top of my head every company that sells autotuners in the ham market (with the exception of SGC, Kenwood and Yaesu) has outright stolen or borrowed some of the innovations that we have come up with.

My guess is there will be more in the future. It's part of how it the system works.

Dwayne Kincaid

Cheap price does not always equate to a value.

When I buy from a reputable company like LDG I receive technical support, repair options and a manual that is not written in Chinglish.

Thanks Dwayne for a reasonably priced product and product support.

It may be possible that SGC acquired design info from SEA. I was only referring to companies that have used designs/features that were first introduced by LDG. SGC was not one of those.

Pierre Goral (from SGC) and I talked many times. At first he was fairly abrasive in our exchanges, but calmed down some after the amateur market shifted to mostly desktop autotuners.

They did reverse engineer some of our products to find cost cutting hardware implementations (moving to 68HC11 processors). However, that most likely would have happened anyway in the natural course of processor capability/cost development during that period.

We had agreed before he passed away that we would not directly compete against each other since we both had found market space. This is an agreement that we still keep today. LDG is typically not a "me too" company, so you will rarely find an instance where we move into market space that someone already has a product.

Is this why LDG doesn't market autocouplers that are designed to be placed at the antenna feed point (in many cases, the absolute best place to locate the tuner in an antenna circuit)?

If so, it's understandable...but disappointing! :)

Hi Kirk,

We have been working on a solution for this case for years (as well as many other projects). Fortunately for us, the vast majority of installations do not require a tuner at the feedpoint (a horse we have already beat pretty well a couple months ago). Eventually, we'll have something that we feel is the correct product for the remote tuner market.

Hi Dwayne, ok;
I have nonetheless always used my old Z11 remoted to the fishing rod base, about ten meters away from the FT817 ; I used to close it in a kitchen box in rainy days, hi, and surrounded by golden cloth during the summer days to protect it from hot sun . It always did a good job. A friend of mines does something similar with a Z11 and his FT957 during /P . They are not buolt for antenna base, maybe, but nonetheless do a great job!
Dwayne, keep the good work on LDG ! You all there deserve great respect for what you did and do. 73 de Augusto HB9TZA / I2JJR
PS What I always wanted but never did, was to mod the Z11 for power supply and tune button thru the antenna cable.
Not strictly needed , anyway, as I did 100th of operations /P with FT817 and Z11 without the mod ..

Topic: 6195 Message: 6195

I have an AT-11 I bought way back in 96 when they first came out. The board is a version 2.1 dated 12/95 and the firmware is version 1.7...

All the capacitors used for tuning are ceramic while I see all the later versions were silver mica.

Also it seems as if the promise to upgrade the firmware has went by the wayside.

I am wondering if the unit is worth completing or if the ceramic capacitors were enough of a problem to make it not worthwhile.

Also can the firmware from one processor be copied to another if I could find a current version?

I have not worked with this processor but I assume that older programmers are still available somewhere. I remember being told that the problem with the earlier versions wee the processor running constantly and creating RFI and the later firmware correcting this by the processor only running while actually hunting for the match...
I actually still have the receipt in the box of parts...

Any help out there.....
Garry

Charley,

Although we have seen reports of getting 10 through 40 meters, that is not typical. I'd say that 75% of mobile installations "do not" get 10 through 40, but only 10 through 20 meters.

6201. Using auto tuner at multi-transmitter (Field Day)

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2013-05-06 19:00:23 UTC
From: w_r_adams1
Topic: 6201 Message: 6201

If it is possible, what is the best way to use an auto-tuner at a Field Day site? We are planning to deploy 4 HF stations including our GOTA one. Matched resonant monoband antennas will be used at 3 of the stations, however, we are considering an 80 meter horizontal loop or 88 foot doublet for the fourth station to be used on 80 through 10 meters. An AT-100 Pro tuner and 4:1 / 1:1 balun is available. Looking through the archives, we may need to turn power to the tuner on and off, but it is unclear as to whether or not this is necessary. Has anyone been successful in using there auto tuner in this context? Please comment.

I was interested in doing some A-B tests. With an Icom IC-761 feeding a B&W antenna switch to choose between the the two antenna setups.
Antenna #1 102' doublet, 450 ohm feed line, 9:1 current balun and Z11 Pro II tuner.
Antenna #2 65' 40 meter dipole about 20 feet below the doublet.

Short answer... When transmitting in the 40 meter dipole, the Z11 Pro II went nuts trying to deal with what it thought was an infinite mismatch. This was due to the power coupled into the doublet antenna from the dipole.

Now admittedly, the two antennas were only 20 feet apart and parallel to one another.

If I make a small assumption; when you transmit and the tuner finds a good match, i.e. minimum reflection, it may STILL be a problem depending on how much RF from other transmitters are being fed back into the tuner.

Such as it is, I would suggest using a manual tuner at this point.

Hi Jeff,

I have experience this issue, the first time it occurred the ATU in question happened to be powered and with no antenna or radio attached!

The solution is to have a very good earth ground on the ATU and to have common mode chokes on the feed lines. It is usually only the lead to the switch box of an active antenna, but depending on the RF fields you are dealing with, often it is the jumper between the radio and the ATU where a common mode choke is also required. Lastly its best to make use of antenna switch boxes that ground all the other ports and all ports when not in use.

Thanks for your replies. Sounds like our best approach, since we can have 4 100 watt transmit antennas operating simultaneously within a 1,000 foot diameter circle, will be to forgo the convenience and advantage of auto-tuning! Even some sequencing method of switching power off when other RF is in the area is too complex to manage for a temporary event. Solution is to send a person with an HT out to the antenna/manual tuner position and have another person with HT at the transmitter when a QSY is required. Bother. . . I really wanted to demonstrate the utility of my LDG AT-100 Pro to my club.

A local ham and friend has the following setup:

204' dipole fed with about 45' of ladderline. Ladderline is connected to a 4:1 balun and coax goes to the shack. Radio is a TS-2000, and he also has an ALS-600 inline.

With this set up he originally had a 600 proII tuner. The SWR on 160 is around 3:1, but the 600 would not tune the antenna. So we did some testing.

1) Tuner in bypass, internal tuner on the TS-2000 tunes 160
2) Put my 200pro in place of the 600 proII and that tuned 160
3) Connected antenna directly to radio, TS-2000 tunes 160 no problem

So we figured the tuner was "bad". He decided to get a 1000 pro II. Recieved it today, that will not tune 160 either.

What gives? The specifications for tuning range are exactly the same for the 200pro, the 600 proII and the 1000proII. My 200pro is obviously older, and purchased from Universal Radio new probably in 2007 or 2008. The 600 ProII and 1000ProII were both purchased from Gigaparts.

Any thoughts?

1. Try a 9:1 current balun. DX Engineering sells them or you can make your own.
2. How long is the coax from the tuner to the balun?

Coax length is LMR400 about 25'
Using an MFJ analyzer @ 1.9mhz:
R=15 X=27 (Z=30) SWR=3.7

These are within the tuner specified ranges. And like I said my LDG-200pro tunes this system without a problem, and the tS-2000 tunes the system without a problem. The LDG-600 and the LDG-1000 cannot. We cange nothing when putting the 200 inline, same coax connections, same ground connection. Something is different enough between the 200pro and the higher power units that is causing them not to be able to tune the antenna.

6210. I want to use the CW key jack of my rig for tuning a Z11 Pro II

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2013-05-09 10:39:11 UTC
From: jjamesj8
Topic: 6210 Message: 6210

Hello all! I was wondering if the CW keying current and voltage were low enough, could I use the CW key jack to key the transmitter during a manually initiated tuning cycle? (press the "tune" button on the Z11, have it key my rig for as long as the tuner needs). I read the radio interface guide and found it pulls the tip of a stereo 1/8 inch phones plug to ground, and can handle apparently about 100mA which it sends to ground while tuning. I wonder if this could be used as a "universal" radio interface. (of course for radios with a CW jack that can handle a straight key and does not pass through a keyer circuit damaged by long key-down)

My radio is a semi-homebrew Atlas 210 IF boards and filters, Swan 350 VFO stabilized by a crystal controlled huff-puff circuit, and Swan transistor finals from a 3rd radio I have not yet identified. It's fun to use if basic, and I get good reports on the air with it. I also use a Radio Shack HTX-10 through an antenna switch before the tuner.

My antenna system is the Z11, RG8x coax feedline, and a mobile mount on a 1/2 inch hardware cloth covered 4 ft tall by 20 foot long metal fence that uses 3 Hamsticks that share the antenna mount via a Hustler VP-1 http://www.hamradio.com/detail.cfm?pid=H0-003467. The bands the hamsticks cover are 80m, 20m, and 15m.
I use the tuner to widen the 60KHz bandwidth of the 80m hamstick I tuned to 1:1 at 3.9MHz (I am a general class here in the US) and enable operation at 40m and 10m without added radiators.

I originally got the Z11 because of the 80 and 40 meter bands driving me crazy with retuning all over the band on my old MFJ-949E, a tuner I could always get a good match on, but never got the hang of without seeming excessive RF pollution. My ground "system" consists of a single 18awg 125ft long bare copper braided wire I strung along the ground outside my home.

Also... should I shorten my ground (counterpoise?) wire by half it's length? I just realized 120 ft is a half wave at 80, so i wonder if my ground wire has a high impedance at the tuner on 80. The fence seems a fine enough ground plane on the other bands.

Thanks for reading and 73s,
KE6DLO

So LDGs response to the support request:

"Hello,

It may be a feedline length issue. Try adding 5 or 10 feet of coax on the antenna side of the tuner right at the tuner.

Dwayne Kincaid"

Can someone explain how it can be the feedline when both my 200pro and the TS-2000 internal tuner work using the same exact feedline going to the antenna as the 600proII and the 1000ProII??

6212. Tech Support Question of the Week/Month

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2013-05-09 20:46:14 UTC
From: Dwayne
Topic: 6212 Message: 6212

From time to time we get really good tech support questions by e-mail or phone. We think it would be a great idea to pass along some of the better ones to the group for dissemination when appropriate.

This week/month, I'd like to talk about some of the questions that we get about the G5RV antenna.

The original G5RV antenna designed by Louis Varney (G5RV) did not have a balun. It simply went from ladder-line to coax. But that was back in the day (the 50's) when ferrite material was not readily available. Also back then, all the transmitters had tubes in the finals, so it really did not matter if the antenna was matched or not. The radio would put out full power into a coat hanger or whatever else you had connected to it.

Fast forward to today and almost all radios are solid state and they need a decent match with a tuner to be able to put out full power. So we have to take a little more care of the feedline and antenna.

While the original G5RV did not have a balun, today we need to protect the radio from RF. So now we "need" a balun or choke in the system to keep any RF from coming back down the coax feedline and messing up the solid state radio.

If you want a good read on this, "The G5RV Antenna System Revisited" by L.B. Cebik is a great 15 to 20 minute read. He verifies that a choke (or balun) is an improvement for today's radios.

From more than a decade of tech support, we've seen very good results with 1:1 current baluns and 4:1 voltage baluns that interface the 450 Ohm ladder line to 50 Ohm coax. Some have even reported that a 9:1 balun does even better since 450 Ohms divided by 9 is 50 Ohms (check out Balun Designs for high quality and high power baluns). Cebik only goes as far to say that only a choke is needed, but I believe this was written some years ago.

The bottom line for today is you need a choke or a balun of some sort at the conversion point from ladder-line to coax for a G5RV to operate properly with your solid state radio and tuner. Otherwise, the coax is now part of the radiating system all the way to your shack.

While there are plenty of companies selling original G5RV antennas that do not have a choke or balun, you'll find that those will not perform as well as the "updated" G5RV that has a choke or balun.

Dwayne Kincaid

I have mentioned this repeatedly.

A G5RV antenna _with_ a balun to coax, or directly to a balanced antenna tuner is a doublet antenna.
It is made reference to in the ARRL handbooks back in the '30s.

Additionally, and this is why Dwayne suggests added 5-10 feet of coax, is because the coax transforms the impedance the tuner sees. (Read up on Smith Charts and transmission lines.)

As to "Well, my OTHER antenna tuner works." That's fine, but NOT all antenna tuners will handle the exact same combinations of R and +/-j.

My comments about using the 9:1 balun with 450 ohm line, makes the entire line appear to be one continuous piece of feed line without any extra transformations brought about by having a discontinuity. For example, 450 ohm lines and a 4:1 balun automatically introduce a 2.25:1 SWR and make the remaining piece of 50 ohm coax look line a transmission line transformer further exacerbating the load matching equation.

We took some measurements tonight to see how each of the three tuners would transform a 50 ohm load at a few different L/C settings at 1.8MHz. I have to some up with a clear way to present it. Hopefully I will post something tomorrow.

Our test found that there was a difference in the impedance transformation, with the largest variation in the inductance. I have not figured out the exact amount of change yet, but it was there, and it may be within tolerances of the components.

From time to time we get really good tech support questions by e-mail or phone. We think it would be a great idea to pass along some of the better ones to the group for dissemination when appropriate.

This week/month, I'd like to talk about some of the questions that we get about the G5RV antenna.

The original G5RV antenna designed by Louis Varney (G5RV) did not have a balun. It simply went from ladder-line to coax. But that was back in the day (the 50's) when ferrite material was not readily available. Also back then, all the transmitters had tubes in the finals, so it really did not matter if the antenna was matched or not. The radio would put out full power into a coat hanger or whatever else you had connected to it.

Fast forward to today and almost all radios are solid state and they need a decent match with a tuner to be able to put out full power. So we have to take a little more care of the feedline and antenna.

While the original G5RV did not have a balun, today we need to protect the radio from RF. So now we "need" a balun or choke in the system to keep any RF from coming back down the coax feedline and messing up the solid state radio.

If you want a good read on this, "The G5RV Antenna System Revisited" by L.B. Cebik is a great 15 to 20 minute read. He verifies that a choke (or balun) is an improvement for today's radios.

From more than a decade of tech support, we've seen very good results with 1:1 current baluns and 4:1 voltage baluns that interface the 450 Ohm ladder line to 50 Ohm coax. Some have even reported that a 9:1 balun does even better since 450 Ohms divided by 9 is 50 Ohms (check out Balun Designs for high quality and high power baluns). Cebik only goes as far to say that only a choke is needed, but I believe this was written some years ago.

The bottom line for today is you need a choke or a balun of some sort at the conversion point from ladder-line to coax for a G5RV to operate properly with your solid state radio and tuner. Otherwise, the coax is now part of the radiating system all the way to your shack.

While there are plenty of companies selling original G5RV antennas that do not have a choke or balun, you'll find that those will not perform as well as the "updated" G5RV that has a choke or balun.

I am assuming the comment below is directed to my thread the 600/1000 not tuning what a 200 will:

> Additionally, and this is why Dwayne suggests added 5-10 feet of coax, is because the coax transforms theï¿½impedanceï¿½the tuner sees. (Read up on Smith Charts and transmission lines.)
>
> As to "Well, my OTHER antenna tuner works." That's fine, but NOT all antenna tuners will handle the exact same combinations of R and +/-j.iï¿½
>

I understand about how coax transforms the impedance, and have spent my fare share of time at manipulating impedance on a smith chart.

Our main problem now is when LDG stands by the comment "tuner is basically the same as the 200, but with larger parts, so you are correct that it should work." Even more baffling is the fact the antenna on 160M is showing an SWR of > 4:1 (R=15 X=27 using an MFJ analyzer), and all other bands work(some with higher SWR, and lower real portions of the impedance, i.e. lower radiation resistance). I would assume if the tuners are the "same" they would handle the same/similar combinations of R and +/-j with out a problem.

It doesn't cause the radio to reduce power. It just uses the TXReq line
for the amp to send start a carrier. If you want to reduce power you
have to do by hand. With that said the radio will fold back power as
the SWR goes about 2:1 during the tune cycle so it will appear that the
power was reduced.

Still a wide range tuner like the 600 or 1000 should be able to tune anything an internal 3:1 tuner can an much more, especially when the antenna impedance is will within the specified "tuning range".

Subject: [LDG-auto-tuners] when 600 PRO off receive sensitivity low

was wondering when I have the 600 Pro off the receive sensitivity is low but when the tuner is on everything is ok I plugged the antenna directly into the rig and it works fine.

Any info on this appreciated

Thanks,

Len

6227. Tuner for S9V43

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2013-05-15 16:39:07 UTC
From: KF4KUL
Topic: 6227 Message: 6227

Hi,
Just got a LDG S9v43 vertical antenna. What would be the best (remote/local) auto tuner to use with this antenna. Have a FT-920 and the internal tuner has problems tuning on 80-6 m bands with this antenna. Yes, I have radials (4 per bands).

Thanks, Udo (KF4KUL)

6228. Low Inventory on S9v31 NOS

From: Dwayne
Topic: 6228 Message: 6228

Just a reminder that we are almost out of the "new old stock" of the S9v31 antennas. These differ from the current 31 foot model that they do not use the plastic clamps, but use metal screws to hold the fiberglass sections together.

At the current rate, our guess is that they will be all gone in the next few weeks. Right now www.cheapham.com has the 31' NOS antenna for $65.00.

Best would be a remote wide range tuner. Unfortunately LDG doesn't make one. The tuners in radios are not capable of handling the high swr of 43 ft verticals. I have a 43 ft with an LDG 1000 pro 2 in the shack. It struggles on 80 but works well on all the other band (using an old Butternut 160 unit as well)

I was troubleshooting my FT-Meter as it was not moving on transmit or receive. Turns out that the part that plugs into my Yaesu FT-857D must have a broken wire on the inside(where the L shaped elbow connects to the radio). I tried another double male cable and the meter works fine. But I need that double male cable for something else.

Question:
So how do I replace the cable. Does LDG sell them separately? If not, what do I ask for when I go to Radio Shack. I noticed that the cable connector itself only had one black line on it. So the must mean something. Let me know. All comments will be appreciated.

Hi Jose,
The one black line is an insulator between two terminals,meaning
that it is a monaural connector.Two insulators would mean that it is
a stereo connector.
You need a cable with 1/8" monaural connectors,and a right angle
connector for the radio end is very helpful.

Not sure about your model but I have a AT-100 Pro II and am having all sorts of problems getting it to work with my long wire. I have added additional grounding to the antenna system but still will not tune up on all bands. I have tried 1:1 and 4:1 Baluns with no luck.

I am going to be mounting a G5RV as soon as the weather clears up and will find out if it works with that.

Watch out with a G5RV. There's a 9/1 SWR at the feed point (maybe higher) of the twin lead on the fundamental frequency(75/80 meters for a 102'model) which many tuners won't match. I won a commercial G5RV antenna at a hamfest a year or two ago, and immediately torn the coax fitting off the twin lead, extendedthe length to a half wave on 80 meters, fed it with more window line, broughtthe window line into theshack, and used either a LDG 4/1 or LDG1/1 balun toconvert thebalanced tounbalanced, With a bit of experimentation with the length of feeders the antenna works fine. Muchbetter than any G5RV with which I've had to suffer.

Three things. Once you remove the directly connected unbalanced coax from the balanced feedline on a G5RV and use an antenna tuner, it ceases to be a G5RV antenna and becomes a 102' doublet antenna. The same one in all of the 1930's editions of the ARRL handbooks.

There IS a specific length involved in both the element (doublet) length and the feed line length. The element is roughly 3/8 wavelength at 80 meters, and the feed line is roughly 1/8 wavelength at 80 meters. This combination allows the antenna to work smoothly from 3.5 to 30 MHz.

Secondly, Use of a current (choke) balun rather than a voltage type is preferential as it forces the current to be the same on both sides of the antenna. This is even more important if you have grounding issues.

Thirdly, If you're using 450 ohm coax, use a 9:1 balun. 450/9=50. There's NO reason to add fixed SWR issues to the feed line.

Jeff:

Oh? Have you read QST, May 1994, page 34 ff? It's a theoretical and
practical analysis of the G5RV

This explains why I've never had much luck with a 102' G5RV on 80 meters.

I rest my case.

72/73 de n8x Hg
QRP >99.44% of the time.

p.s. I know the definition of a center fed resonant dipole, and that
G5RV is a specific version of a dipole. The originator of the antenna
designed it for 20 meters, NOT as a multi-band antenna.

6247. TS-990 Update

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2013-06-12 17:24:14 UTC
From: Dwayne
Topic: 6247 Message: 6247

Hi All,

We've been playing with the new TS-990 here for a couple of weeks and found some interesting items.

First, the meter on the radio is almost an exact copy of the old DM-7800 that we did a few years ago. Kenwood also added a meter port on the back, so you can connect an external meter to it. Since Kenwood does not make one, we'll have one in a couple of months. It will be the DM-990 and have a list price of about $179.99.

Secondly, for some reason, Kenwood still limits the RF power to 100 watts if it detects an external tuner on the tuner port even though the TS-990 is a 200 watt radio (just like the TS-480HX). We think that there should be a letter writing (or e-mail) campaign to Kenwood to ask for a firmware change that allows the TS-990 radio to transmit 200 watts even with an external tuner connected. If we can get them to change that, we'll make a 200 watt tuner with a Kenwood interface (something like KT-200).

The reason (that we think) that they limit the power is that the only external tuner that they made (the AT-300) only did 100 watts. However, it's been discontinued for many years and it's time that the interface allow newer external tuners.

We don't have a Kenwood contact, but I'm sure one can be found.

That's it for now,

Dwayne Kincaid

Karsten,
I have had a Z100 for several years and used it with many antennas.
It is good with G5RV, full wave loops, verticals and long wire kite antennas. 60 to 65 meters is a good length.
It has more capacitance inside than inductance so if the antenna is inductive at any frequency it is better.
If the antenna is capacitative you may need to add some L.
Andrew

I was using the dummy load to check that the radio was working correctly. The AT-600 is acting very weird. It won't tune any antenna I have and it causes the TS-590 to show an extremely high SWR. I still have an AT-200, so I connected it and it tunes everything as it should. Maybe time to send the AT-600 in for testing.

My AT-200Pro works all the time, everytime. I wish I could say the same about my less than 3 month old AT-600Pro. This is my third LDG tuner and the original AT-11 would tune anything but can't say the same about the AT-600. It is just too intermittent.

The AT600 doesn't want to tune things the AT100 and AT200 have no problems with. :(

Seems to be a common theme here as of late. The 200 and below tune what the 600 and up will not. Something is obviously different in them enough to be causing problems beyond the manufacturing acceptance/verification testing.

We really need to do some side by side comparison testing of these tuners with known loads and see if the different models get the same tuning solution.

It's not an excuse, it's simple physics.
An understanding of transmission line theory and Smith Charts would help you to see this.
Secondly, if an AT-600 was identical to an AT-200 it would have an AT-200 label on the front.

Wide range antenna tuners, especially automatic ones are great, but the common myth that they
will tune up everything from a bed spring to your wife's panties is a misconception.

You can make any argument you want about smith charts but bottom line is
tuning range for AT200Pro2, AT600Pro2 and AT1000Pro2 is 6-800 ohms. As
a consumer you would expect them to tune the same load. Since they
don't there is a difference and this equates to a consumer dissatisfaction.

Well put I see lots of chatter about this tuner, Iwonder how many people are reading there manuals and also checking out the basicre transmission lines and impedance matching in the ARRL handbook for example.
Understanding smith charts or using a rf bridge to see what exists at the tx end of the transmission line a MFJ analyzer does not necesssarily tell you everything.

An older ham elmer ham told me over tweny years ago get your antenna and feedline as close to perfect and you will avoid alot of problems.

Refer back to antenna matching theory in the ARRL handbook. maybe some of the teaching instructors are miising this in todays theory during ham calls lectures

By load you need to include the reactive factor where you have a real and reactive components (resistive component then the reactive part eg xl or xc component both of these make up your antenna .

Every persons antenna installation is not likely ideal ,soil resistivity, wet or dry conditions, closeness to grounded object metal or tees for examples.

RF will leak to ground remember the E and I factor in power formulas insulation principals and property of materials used glass vs plastic insulators for example also the materials the manufactures pick in the anntena construction.

Tuner components also have limits in what they can correct to.

The real problem is that LDG has stated "the designs are the same, just the components are rated for higher power" All things equal, If the 200 and lower have A,B,C value capacitors and X,Y,Z value inductors and the 600 and up have the same "values" then the tuning range should in theory be the same. The smith chart does not take into account power rating, it is only impedance, and moving an impedance to get a match only depends on the impedance/admittance of the components used, or the transmission line lengths involved.

If the values of the Ls and Cs used are the same within some tolerance, the only thing that I can think of that is causing the difference in tuning range would be the relays, and the lengths of the transmission lines used to interconnect the components (both Ls and Cs as well as the relays and input/output connectors). It is apparent from my experience with the higher power tuners it appears to have more trouble with low values of R (the real part).

Good afternoon everyone. I'm new to this group. I have an AT-897 plus and a Z11ProII in use now and just acquired a YT-100 used for an FT-100D that going to run Mobile. The cover of the YT-100 is badly scratched so I wanted to at least check the cost of a new cover with LDG. They don't seem to be geared up for part sales. Am I forced to go through a distributor or have I missed something on their website? 73 Dean KC3Z

Dean,

The lid for the YT-100 (as most lids) is a part that we do not carry. There are no distributors that carry lids.

Mr. Kincaid,

Thank you for responding. I was under the understanding that LDG actually made auto-tuners...and in the USA. LDG tuners are significantly better units than what the radio manufacturers offer.

I also sort of assumed that if LDG made the tuner that they would surely fabricate the sheet metal. If my assumptions and understandings are correct; why wouldn't you good folks sell the covers? In general, the ham community is VERY particular with regard to the appearance of our equipment. Stacking equipment and operating mobile often puts scratches and other undesirable marks on the covers of our gear. I know that we would pay good money to replace them...so why would any good business person ignore this market???

Hi Dean,

Sorry to disappoint, we don't do everything! We outsource the enclosures and the PC boards and have been for over a decade. A long, long time ago, Ten-Tec made our enclosures, but their quality went down and the price went up (which happened a lot in the 1990s).

Over the years, we've had many, many companies make the enclosures and PC boards.

It's possible that our units are better than others, but we have not seen any quantitative information to back that up. We have a continuing passion to improve quality and value all the time and we hope that it shows in our products.

Occasionally, we will have a scratched or dented lid or chassis that does not pass our QC and those units will be sold at a discounted price through www.cheapham.com. All units that pass all QC checks become production units that go to all distributors.

I hope this help understand the process,

Dwayne Kincaid

The fact that I bought my AT100 Pro II through CheapHam and the fact that units that do not pass all QC tests go there for sale probably explains why I still can't get mine working. I have added grounding, repaired cables, checked the shack for RF leaks and no luck.

I was going to sell it on eBay but now not sure I want to pass on a less than quality product to another ham.

Hi Walt,

I think you misunderstood the statement. We do not ship any units that do not pass all "functional" QC tests. However, we will send units that have cosmetic deficiencies (as this is what this thread is about) to CheapHam to be sold at a discount.

All units, even the ones with imperfections on the enclosure, carry a full warranty.

Dwayne Kincaid

6269. YT-450 and CAT control problem ?

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2013-06-21 21:19:37 UTC
From: Demetre
Topic: 6269 Message: 6269

I recently purchased a YT-450 to go with my FT-450D.
The tuner works OK as long as it is used without a computer connected for CAT control.

Once a software such as MixW (PC) or Fldigi (Mac, I tried this with both PC and Mac) the tuner will not initiate a tuning cycle ! What I concluded is that the RTS flow control isn't reported properly when a computer is connected.

Has anyone experienced this problem ? is there a fix ?

Thank you once again for your response. I really like Cheapham and would have no problem buying an LDG product in the "scratched and dented department (mfg refurbished)" with your full warranty.

I confess sir, that I'm still trying to get my arms around you as a person on this forum and where you might fit into my needs as an LDG customer. Yes sir, I did say and mean my needs. May I ask, is part of your job at LDG Electronics responding to queries from this forum?
May I ask what is you job title? And finally, are you an active Amateur radio operator? I'm pretty sure that the answer to my last question is no. I say that because you are seeking a "qualitative proof" of LDG's superiority with Auto-tuners. Really?

The only real question that I need answered is does LDG offer a touch-up paint for tuners. If the answer to that is NO, then LDG really needs to get in touch with the ham community because truly, LDG doesn't know us. Dean KC3Z

If you take the time to look, you'll find that Dwayne has an Amateur Extra Class license. You'll also find that his mailing address is the same as the mailing address for LDG Electronics.

As to touch up paint, mostly it's black. How difficult is that?

Hi Dean,

I'm not going to answer the superfluous questions. One of the rules of this board is that you must remain civil and you are on the borderline of that.

If it were me and had a badly scratched lid, I'd properly sand the lid and use some flat black spray paint from your local hardware store. Since we use close to flat black, it would give you a very close match.

If it were a small scratch, a wide tipped black sharpie can be used. Draw on the scratch and then lightly wipe away the excess with a soft cloth or tissue.

Thank you once again for your response. I really like Cheapham and would have no problem buying an LDG product in the "scratched and dented department (mfg refurbished)" with your full warranty.

I confess sir, that I'm still trying to get my arms around you as a person on this forum and where you might fit into my needs as an LDG customer. Yes sir, I did say and mean my needs. May I ask, is part of your job at LDG Electronics responding to queries from this forum?
May I ask what is you job title? And finally, are you an active Amateur radio operator? I'm pretty sure that the answer to my last question is no. I say that because you are seeking a

"qualitative proof" of LDG's superiority with Auto-tuners. Really?

The only real question that I need answered is does LDG offer a touch-up paint for tuners. If the answer to that is NO, then LDG really needs to get in touch with the ham community because truly, LDG doesn't know us. Dean KC3Z

Hello Dean,

Please send me a list of the ham companies that supply touch-up paint, I've never heard of this being offered in my 55 years as a ham.

Joe

I'll just add how impressive it is that the owner of the product actually takes part in the group. That's gives users of the product a direct line to the owner. It's sure uncommon. And it means that he gets the beefs as well as the thank you notes. I believe he has handled himself really well when responding.

Dean,
you don't have the foggiest idea how much customer oriented LDG company is. There are countless examples here, and countless not even listed here.

I will give just one. I own a AT-100 Pro and tried to get the free balun offer, but I had to send original receipt back. They accepted the scan of the receipt instead and the balun came some days after. In ITALY.

It is so customer oriented that probably a nearby ham would paint to you the box just to avoid you keep nagging LDG. Where are you based?

6280. On a brighter note:

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2013-06-23 13:53:40 UTC
From: Furliips Stardust
Topic: 701 Message: 6280

I'm using a Z-11 ProII tuner with a 9:1 balun, 450 ohm window line and a 102' doublet antenna at 35' in an inverted-vee configuration.

This is what I've heard over night and this morning from Central Texas on 20 meter PSK31.

1) Summary by Continent and Country (14)

Callsign	Time	Band	Country
UA0CBM	02:24	20m	AS Asiatic Russia
JR1EMO	04:16	20m	AS Japan
OK1PJB	02:52	20m	EU Czech Republic
DJ5VB	02:57	20m	EU Fed. Republic of Germany
F6ECI	02:43	20m	EU France
IW6CZF	02:44	20m	EU Italy
VE3MIS	06:48	20m	NA Canada
KP4FD	04:17	20m	NA Puerto Rico
W3AO	06:50	20m	NA United States
NP2VI	05:05	20m	NA Virgin Is.
WH2HAO	02:26	20m	OC Guam
LW1DQQ	06:45	20m	SA Argentina
HK6ONG	23:53	20m	SA Colombia
YV4DHS	06:44	20m	SA Venezuela

I'd say the tuner is doing an excellent job.

I for one will vouch for the customer service of LDG, I sent two Z100 auto tuners from Australia back to the USA to be repaired, both tuners are well out of warranty and I have had plenty of use with them. One of them had been modified so I could use it remotely while mobile.

Both tuners had been fixed and returned to me at no charge. This is a great way to keep customers happy and I will definitely purchase LDG items again.

Cheers to the crew at LDG Electronics for their outstanding customer service. WELL DONE

Cheers

Hi Dean,

I'm not going to answer the superfluous questions. One of the rules of this board is that you must remain civil and you are on the borderline of that.

If it were me and had a badly scratched lid, I'd properly sand the lid and use some flat black spray paint from your local hardware store. Since we use close to flat black, it would give you a very close match.

If it were a small scratch, a wide tipped black sharpie can be used. Draw on the scratch and then lightly wipe away the excess with a soft cloth or tissue.

Used LDG AT-100pro at Field Day this weekend and it worked flawlessly on 150 ft long wire on nearly all bands. Matched so fast we got suspicious and put dual needle Daiwa meters before and after to check and match was fanatastic. Worked significantly better than internal tuner on Kenwood TS-850 handling the long wire.

Great tuner that works. As one guy said "it matches stuff that probably shouldn't be matched".

I use much of my gear on location so scratches, scuffs, and the occasional ding does not necessarily denote abuse, just that the equipment has "experience."
In my opinion, if a piece of equipment has no signs of wear, it shows that perhaps the owner: 1. never used it 2. it never left the shack (OK) 3. the owner is obsessive about appearance. Obsessive being use in place of another word beginning with "A".
My concern in buying used or refurbished gear is not what it looks like, but does it work properly.
Dwayne helped me with a tuner that did not work properly by e-mail troubleshooting and then by repairing at no charge. I admit that the problem may have caused by something dumb that I did but I like to think it was a weak component that cratered.
LDG is FB!

Travis/All:

I bought a Z-100 from afellowwhohad left it in the rear window of his truck one too many times. The case iswarped to such an extent that I need to use electrical tape to hold it together. He gave it to me with an "offer I couldn't refuse" and a guarantee that if it didn't work (electrically) that I needn't give him a check the next time we ate lunchtogether.

Cosmetically it probably would rate between -10 and 0 on a +1 to +10 scale, but it works like a champ!

Best$40 I ever spent on a tuner!

Oh, yes, Dwayne told me they didn't stock the cases any more, but he told me where to go to find a new case, and it's still in production for about $9.00 plus postage, but I've not bothered to do so yet! I do note that the Al-100, about to be released by LDG for Alinco rigs, mayhave the same case, so theycases might be back in stock @ LDG! I'll have to inquire again.Dwayne is a gem of a customer service rep!

From: Hank Greeb
Topic: 701 Message: 6290

Hi Dwayne:

I see an ad for the upcoming AL-100 tuner on the opening page of the LDG web site. Is this tuner in the same case as my old Z-100 which I got from a friend? It came with a case which is beyond restitution, but the price was right, and it works FB electronically!

If so, what's the price for a new AL-100 case?

I've been procrastinating for a couple years on purchasing a case from the vendor who you so kindly told me about.

I'd buy a case in a heartbeat from LDG. :)

Check the manual.
http://www.ldgelectronics.com/assets/discontinued_manuals/rt11.pdf

Especially see page 3 where it discusses the use of pins 3 and 4, and
"Even if you provide no control circuit for your RT-11, you can still
use it by putting the tuner into
fully automatic mode. This is done by grounding the Auto/Semi pin during
power up. The tuner is
then in Auto mode, without needing a control circuit. LDG does not
recommend this method, as it
affords the operator little control over the tuner, but it can be useful
in some circumstances."

Tony, was the long wire fed with a balun or directly into the AT 100 pro?
I use one here with coax fed multiband fan dipole and it is great.

Don, we started out with a 4:1 LDG balun and had a good match. the 4:1 was used because it was there - no compelling reason.

We ran about 100 ft of RG-213 to the balun at the end of the long wire. We used a Radio Shack short 4 ft ground rod about 3 ft away from the balun. The balun was about chest high above the ground connected to the long wire that and then went up vertically into a tree to a height about 30 ft., then out to another tree. Total length was about 150 ft.

The guys then experimented with an MFJ current balun at both 1:1 and 4:1 and found the 1:1 worked best.

We had very good match with about 70 watts out of radio. Power was low because batteries we used were around 12.2 v on the TS-850.

I have 2 LDG tuners. The AT-100 pro and a Z-100 on my Icom 706 MK II G.

They work. They work very well!!! If I buy another auto tuner it will be an LDG.

I'm very interested in this application of the AT100. I assume you were in semi-automatic mode. Was the ATU local to the transceiver or remote at the antenna?

What was the field day configuration
1. transceiver > 100 ft. Coax > AT 100 > ground & balun > 150 ft. Wire or
2. transceiver > AT 100 > ground & 100 ft. Coax > balun > 150 ft. Wire or
3. Something else?

Were other antennas or transmitters nearby? Did they initiate undesired tuning cycles?

6298. What's a "good" SWR"

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2013-06-25 11:09:29 UTC
From: w3qt_mike
Topic: 6298 Message: 6298

I'm new to auto tuners after 48 years with manuals, so my question comes from that background as I'm learning. What is considered a "good" SWR after tuning? I'm not obsessive about flat SWRs, but just want to make sure I'm using my AT-1000PROII correctly. Sometimes I do see some transceiver fold-back (My PROIII starts to squeal when I go over about 1.5:1). I'm seeing a range of 1.3:1 to 1.8:1 after tuning, whether I'm tuning a zepp or an LPDA. Some bands are flat others no so much. Fifteen meters on the LPDA seems to give the tuner a hard time.

I'd be interested in what others are seeing after tuning. What's a "good" SWR according to the tuner? Are my ranges about where you are? As I said, my experience has been with manual tuners where you take it down to 1:1. 1.3:1 is certainly a good to go SWR while 1.8:1 starts to trouble the rig. I'd like to check that I'm using the tuner correctly and adjust my expectations. Any input would be welcome.

From: Stephen Finch
Topic: 6298 Message: 6299

I☐m surprised that 1.8:1 SWR causes any problems with your rig at 1.8, the reflected power is about 7.5%. That means that for 100 watts out, 7.5 watts are reflected. That is about 0.37 db.

I generally accept anything 2:1 or less as okay. At 2.0:1, the reflected power is about 11% or 0.5 db. I have my auto-tuner set for a match of 1.5 to 2.0 depending on the antenna. For my G5RV, I can get a 1.5:1 match quite easily. On my off center dipole, the 15 meter band can become a problem so I increase the tolerable match to 2.0.

So, I guess, operate your antenna tuner to give a match that your rig accepts without any ☐complaints.☐

I have the threshold set to 1.5:1 on all my LDG tuners. I`ve found that most radios that had a internal tuner start folding back around 1.5 when you disable the internal tuner.

Tuner was at transceiver connected with about a 3 ft jumper then to coax, balun, ground, antenna etc. We tried putting tuner at antenna end and it was little better but it looked like rain and tuner was not weather proof and it was my tuner so we went back inside. Tuner at antenna end would be best but that is problematic with a normal indoor tuner. ----- Original Message ----- From: w_r_adams1@... To: LDG-auto-tuners@yahoogroups.com Sent: Tuesday, June 25, 2013 7:27 AM Subject: Re: [LDG-auto-tuners] For what it's worth I'm very interested in this application of the AT100. I assume you were in semi-automatic mode. Was the ATU local to the transceiver or remote at the antenna?

What was the field day configuration
1. transceiver > 100 ft. Coax > AT 100 > ground & balun > 150 ft. Wire or
2. transceiver > AT 100 > ground & 100 ft. Coax > balun > 150 ft. Wire or
3. Something else?

Were other antennas or transmitters nearby? Did they initiate undesired tuning cycles?

Steve,

Thanks for the reply. Sounds like I'm getting similar results. I was a bit surprised when I started paying closer attention with this new tuner that fold-back began around 1.5:1 as I always assumed 2:1 as a rule of thumb. Others are seeing the same thing, so it's probably not a glitch in this rig. OK on your floor of 1.5:1. The AT-1000ProII has a floor threshold of 1.7:1. Looks like they raised it a bit, perhaps a tip of the hat to auto-tuner limitations? Thanks again for the reply.

Leonard,

I appreciate your reply. Unfortunately the floor threshold on the AT-1000ProII is 1.7:1, so it's pretty easy to begin folding back even with the tuner satisfied. They must have raised it a bit from other tuners. Not quite certain why except for maybe a little extra margin for higher power? Thanks for your info.

Thanks Tony,

Yours was a good practical deployment. The only wx threat we had here in Texas was heat and wind so I remote deployed my AT100 at the antenna end of a 130 ft. length of 1/2 inch 50 ohm coax. The tuner, battery and balun were on a folding table at the base of the center mast supporting an 88 foot doublet connected to the tuner through a 4:1 balun and a 30+ length of homebrew open wire feed line. We ran the AT100 in semi auto mode (we think, sun too bright for seeing the leds!) but had some mechanical difficulty as wind kept blowing the open wire feeder, balun and tuner off the table! After the third time, we gave up and took my AT100 out of the circuit and started using an internal tuner in our K3 transceiver. Perhaps we also experienced some difficulty dealing with the 2 other active transmitters in the field on different bands when in semi auto mode, but never actually confirmed that suspicion. Food for thought for next year!

The older tuners had the default set to 2:1 but it is simple to set it as low as 1.1:1. Not sure on 1000Pro2 but the other tuners I have use Func-L Dn to set.

Yes. Any reflected power the tuner sees will be assumed to be caused by SWR. Regardless if the power _is_ reflected or if it's coming from another source. I.e. a second transmitter.

When I switch from the doublet antenna with the LDG Z-100 Pro II to the "reference 40 meter dipole" the tuner goes nuts trying to tune the doublet based on the reflected power it sees. (The dipole is connected directly to the transmitter, and the LDG is still connected to the doublet antenna.)

Tony,

I would really like to know as I have been trying to get my AT-100Pro II working with a 100' end-fed long wire with little or no success. I have used a 4:1 Balun and a 1:1 Balun with no noticeable difference.

What was your ground configuration?

Right now, my LDG is basically a boat anchor.

Oh, by the way, it also does not work with a G5RV that my Kenwood TS-440 auto-tuner can handle.

Thanks

Leonard,

I think you are confusing the starting threshold setting in Auto mode to the final match that the tuner finds.

Since our specification is that the tuner will find a 1.5 SWR or less if the starting SWR is 10:1 or less, it makes no sense that the starting threshold be 1.5 or lower.

The issue would be that if the tuner found a correct match at 1.5 and you have the threshold set to 1.5 or lower, the tuner would continue to tune every time you presented RF to the tuner.

We accidentally released a couple of versions of firmware for a couple of models that allowed the threshold to be set to 1.1, but they were later corrected. We did not issue a recall or initiate an upgrade program as the user could still adjust the starting threshold to 1.7 or higher.

From: Dwayne
Topic: 6298 Message: 6311

Mike,

The tuner has absolutely nothing to do with the fold-back level of the radio. If your radio starts to fold back the RF power when the SWR is 1.5, then it's most likely the radio is not calibrated properly.

Any modern solid state radio should tolerate an SWR up to 1.7 to 1.8 before it starts to fold the RF power back.

For those of you that will be checking this tonight, be sure to go by the SWR on the radio to check the SWR where the fold-back starts. It makes no difference what the tuner thinks the SWR is. The goal is to make the radio happy so it can put out the maximum amount of RF power to the antenna system.

Also see my other post on why the lower limit of the Auto mode threshold is set to 1.7.

My 1982ish Drake TR-5 will handle full power up to SWR=2.0 (at least).
Folks who design rigs without a suitable safety factor, like SWR=3.0
maximum, should be sent back to training school.

Of course, I come from a time when pi-network output was still a novelty
on many/most rigs, and variable link coupling was common. Very few hams
paid attention to SWR. My father, as a demo, built a swr "meter" which
consisted of 300 ohm twin lead, and two dial light bulbs, one to
"measure" forward power and the other to "measure" reflected power.
But, most of the time this wasn't used. Instead he would tune the rig
for a dip of the finals, then touch the antenna with a fluorescent light
bulb, and tune for maximum brilliance consistent with a discrete dip in
the plate current of the finals.

Topic: 6298 Message: 6313

Just ran the test on my ft950. Full power out at 1.5:1 reduced power at 1.7:1 indicated on the radios meter. I've seen the same behavior on other radios with built in tuners. They seem to be engineered that the built in tuner will get things below 1.6:1.

In my mobile I did move up to 1.7 as the wind was changing the loading enough that it caused random retunes. Even at 1.7 I get it but the older 857 starts folding back if I go any higher.

I guess your answer kind of explains why the AT600 I bought can't tune things the AT200 had no problems with. I just assumed they would both work with the same 1.5 threshold on the same antenna but the AT600 won't always find a match when the AT200 would get 1.3 or better.

Hello Leonard,

I believe you still have the final SWR match confused with the starting SWR threshold setting for Auto mode.

The two tuners should have approximately the same tuning range. If they are not in the same ballpark, one of them could be out of calibration.

Dwayne Kincaid
LDG

Topic: 6298 Message: 6316

Dwayne,

Thanks for the reply. I understand that the tuner has nothing to do directly with the fold-back level of the radio but indirectly it does by "fooling" the radio into seeing an acceptable transmission line impedance so it doesn't fold back. With the AT-1000ProII I'm making the switch from manual to an auto tuner. I asked about SWR to get a feel for what others are experiencing. My primary concern is on 15M where it doesn't seem to tune as well as the other bands when I'm on my LPDA. Since I'm new to auto-tune I wanted make certain it wasn't operator error. It just might be a calibration issue. I did some brief testing and noticed that the radio's SWR is usually a unit or two higher than the M-1000 reading, so when I was talking about a 1.5:1 to 1.8:1 on the M-1000 the rig was seeing a bit higher. (Nice easy read meter, by the way) I'm going to log that for a while and see if there's a pattern there. Thanks again for the reply.

Topic: 6287 Message: 6317

Wow! sounds like a mess. We have moist [standard fertile]soil and used a 4 ft Radio Shack ground wire because it was temporary. At home I use a 4 ft std ground rod made by cutting 8 ft in half and sharpening on grinding wheel.

To test put an swr meter between the radio and tuner. Then go from the tuner to an antenna or load etc.

Try a 50 ohm dummy load and see if it tunes. If you can find one use a 2:1 or 3:1 load to test. I made a 3:1 dummy load to test radio tuners.

If you are in a real high RF field [close to AM broadcast] you could have issues.

Sounds like you may have a tuner problem.

Tony,

I would really like to know as I have been trying to get my AT-100Pro II working with a 100' end-fed long wire with little or no success. I have used a 4:1 Balun and a 1:1 Balun with no noticeable difference.

What was your ground configuration?

Right now, my LDG is basically a boat anchor.

Oh, by the way, it also does not work with a G5RV that my Kenwood TS-440 auto-tuner can handle.

Thanks

73 de N7MCH Walt

Tony,

Thanks for the advice. I actually have not tried it into a dummy load. Time to read radio for dummies again. :-)

Right now I am running 3 8 ft rods into the ground near my septic tanks all tied to a single point and fed into the shack. In the shack I have a ground strip connected to the ground feed and all equipment tied back to that.

Thanks

Topic: 6319 Message: 6319

Hi Folks

I have Kenwood 590 connected to an AT-200Pro II connected to an Alpha Delta DX-LB Plus.

I have reviewed the manual, but am not clear about the bypass LED.

It seems to stay on as I am tuning various bands.

As I moved between bands how to you reset this LED?

I understand that if the SWR is very low the tuner will bypass.

If the SWR is high on another band will the LED go out and the tuner activate?

Thanks

You don't really need it. The Y-ACC cable does the same thing. LDG
even shows you the schematic to build your own.

Has anyone made the horrible mistake of, during the factory default reset procedure, briefly applying power to the radio connector on the back?
I do not use the radio connection, however since the above action occurred, the tuner does not tune. All the LEDs light up left to right, then all Flash.
I opened the cover and found no evidence of anything burnt.

Any help would be greatly appreciated... looking for schematics too.

Thanks and 7 3

If your light says Bypass after transmitting then your antenna doesnt need a tune - that is a good thing! If lets say your SWR is reading 2.0 and you want to to force a tune, hold down the bypass button for 4 seconds (while transmitting a constant carrier) and it will FORCE a tune... It may or may not go into bypass mode. If it does then you have still an acceptable match based on the threshold set. If you want to lower the threshold say to 1.5 you can do this by hitting Func. key then hitting the Thresh Key... Keep doing this until the SWR bar hits a number that you want it to trigger/force an auto tune.

I too had this question when I first got the tuner... I could not understand why it would almost always go into bypass, I thought it was broken.. In reality it meant that my antenna was well tuned... When I put up an antenna that is not all that resonant it almost NEVER goes into bypass unless I force it (and turn off auto tuning).

Bypass is a nice feature that allows you to "bypass" the tuner to see what the actual SWRs are without the tuner in-line. Its Bypassing the tuner! The tuner is intelligent enough to know that if there is a good match to the antenna to "bypass" the tuner. The tuner will always add loss (albeit not much) and bypassing the tuner will be more efficient.... BUT BUT BUT... this depends on your receiver. Most yaesus start to fold back power at 1.8 SWR... therefor if you have a 2.0 and can get it to 1.1 with the tuner, theoretically its more efficient to have a 1.1 with the tuner than a 2.0 where by the transceiver is folding back a few watts AND potentially a greater mismatch. I have confirmed this with my FTDX3000 using a power meter at the antenna side that more power is getting to the antenna with a 1.1 than a 2.0 without the tuner. I set my threshold to 1.7 because of this finding... Even if I get a good tune to 1.7 or 1.5 I can almost always get a 1.1 but using the C or L buttons to tweak the results.

You might want to call LDG. When I probed a K-Ott the tuner side pretty matched what the 857 does.

It the interface spec available for the RT11 since that it the reason the person needed the Y-OTT for? When I looked at the tuner side of a K-OTT I seem to remember there was two lines, one would put the tuner into tune mode when it was pulled to ground and the other was used to signal the radio to go to tune mode by pulling the line to ground.

How do you do a reset on an LDG AT-1000ProII ?

I could not find it in the manual.

Thanks

I do not believe that you can reset it.

Thanks for the feedback.

If I am on a band and the SWR is low and the bypass LED go ON, then I switch band to a poor SWR will the tuner automatically attempt to tune and the LED goes off.

>
> If your light says Bypass after transmitting then your antenna doesnt need a tune - that is a good thing! If lets say your SWR is reading 2.0 and you want to to force a tune, hold down the bypass button for 4 seconds (while transmitting a constant carrier) and it will FORCE a tune... It may or may not go into bypass mode. If it does then you have still an acceptable match based on the threshold set. If you want to lower the threshold say to 1.5 you can do this by hitting Func. key then hitting the Thresh Key... Keep doing this until the SWR bar hits a number that you want it to trigger/force an auto tune.
>
> I too had this question when I first got the tuner... I could not understand why it would almost always go into bypass, I thought it was broken.. In reality it meant that my antenna was well tuned... When I put up an antenna that is not all that resonant it almost NEVER goes into bypass unless I force it (and turn off auto tuning).
>
>
> Bypass is a nice feature that allows you to "bypass" the tuner to see what the actual SWRs are without the tuner in-line. Its Bypassing the tuner! The tuner is intelligent enough to know that if there is a good match to the antenna to "bypass" the tuner. The tuner will always add loss (albeit not much) and bypassing the tuner will be more efficient.... BUT BUT BUT... this depends on your receiver. Most yaesus start to fold back power at 1.8 SWR... therefor if you have a 2.0 and can get it to 1.1 with the tuner, theoretically its more efficient to have a 1.1 with the tuner than a 2.0 where by the transceiver is folding back a few watts AND potentially a greater mismatch. I have confirmed this with my FTDX3000 using a power meter at the antenna side that more power is getting to the antenna with a 1.1 than a 2.0 without the tuner. I set my threshold to 1.7 because of this finding... Even if I get a good tune to 1.7 or 1.5 I can almost always get a 1.1 but using the C or L buttons to tweak the results.

Hello all!

I have an IT-100 and an AT-200ProII, that I use with my IC-7000 (the IT-100 when out, and the AT-200 at home).

Recently I was able to get an ft-857D.

Is it possible to use the IT-100 with the YAESU, manufacturing a different cable/connection, or the inside interface is completely different?

Thks

Regards

José

Hello,

None of the current LDG tuners have a full reset. The reason is that if you change antennas, the tuner will sense that and do a full tune each time you tune a new band. So in effect, the tuner is constantly looking to reset each memory position, but only if needed.

Jose,

Sorry, there is no way to use the IT-100 with any brand except Icom. You can use the AT-200ProII with the FT-897D.

Look just the gear needed for my new 80 & 160 metre vertical I am making.
Price looks good too. USD200 means it will probably sell in the UK for GBP200. Why I don't know but it always seems to work that way.
Great work Dwayne!

Topic: 6340 Message: 6343

It would be interesting to repeat these tests with 25 ohm, 12.5 ohm, and maybe down to 10 ohms of resistances for 2:1, 4:1 etc, respectively. Reason being a short vertical (or mobile whip) can, but not always exhibit very low impedances that some tuners will not tolerate. If it did, that might be another marketing advantage over a bigger and more expensive screw driver type antenna in a mobile environment. And I'd be very interested in one.

Topic: 6340 Message: 6349

It will tune down to at least 10 ohm resistive and may go further but when I was playing with it, I didn't have a SWR analyzer and could only do resistive loads accurately. Unfortunately I only had a day to play with it before I had to pass it on to someone else in the club. I noticed they are using it as the center of a dipole. See our club web site at http://westmorelandhamradio.weebly.com/check-out-the-new-ldg-tuner.html At Field Day this year we used it as the center of a 10 meter dipole and even then it would tune up on 80 meters. It really is a great product and I am definitely getting one.

> It would be interesting to repeat these tests with 25 ohm, 12.5 ohm, and maybe down to 10 ohms of resistances for 2:1, 4:1 etc, respectively. Reason being a short vertical (or mobile whip) can, but not always exhibit very low impedances that some tuners will not tolerate. If it did, that might be another marketing advantage over a bigger and more expensive screw driver type antenna in a mobile environment. And Iâ☐☐d be very interested in one.

Hello Dwayne and all!

I subscribe that Keith!

My humble opinion:

Good concept. Very good work. Nice requirements gathering ;) !

I hope that will evolve to a good set of tech devices (100W, 1Kw,etc)!

Regards

Jose

After experiencing poor reliability with an MFJ-927 remote tuner and high SWR with an SGC SG-237, I would definitely be interested in an LDG remote tuner for my 43 ft vertical. My LDG Z11-ProII tunes it well from the shack, so a remote version would be ideal. I look forward to this product being in production. Keep us informed.

Cold WX operation??

Any tests yet of how it will work at -30 to -40F ?

(It gets cold in my part of Canada!)

If it will get more power to my antenna, I'd like to put one in my shed where I can eliminate the balun.

Is there a problem with the current line of LDG tuners that are automatic and battery operated being used in a remote location after they are waterproofed? Will they hunt too much or what in the auto mode?

6356. LDG_Z11 Pro Schematic/Parts list

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2013-07-27 17:03:14 UTC
From: k2lrv
Topic: 6356 Message: 6356

Does anyone have a schematic for a Z11 Pro PCB version 1.5, firmware 1.3? I picked up a non-working one, and the MCU appears to be functioning fine, but any attempt to tune or adjust an L or C and all I get is a faint audible whine from a relay. I suspect it is U4, but Q1 also seems to have a lump in the top of it. With no schematic to go buy it makes troubleshooting hard.

I located a replacement U4 already, so if I had atleast a parts list I can do more troubleshooting.

Thanks,

Lou

Think you'll find LDG policy is not to make schematics available

If you return it to them I believe they will repair/upgrade it at a nominal cost

Fine if you live where postage/customs both ways doesn't cost more than the repair or replacement

I have an original Z-11 (not Pro) - the manual on-line at the LDG website has a schematic for this model, it's possible it may be close enough to help you.

There are other manuals on-line at the LDG site. I looked at manuals for other models, older ones have more technical information than newer ones. The reprint of the QST article describing the original AT-11 (which was apparently sold as a kit) has circuits and explanation of the circuits.

I too am having the same issue. I bought a AT-600ProII and have an older AT-200Pro. If these were the same design only with beefed up parts in the why can't the 600ProII tune?

Should have done more research before I bought it. Starting to lose my faith in LDG.

I have since reconnected my Pro-200 and it tunes all bands on my Butternut HF-10V (9V with 160 meter coil).

I bought the Pro 600 since I am trying a 600 Watt amp. Have to keep the amp around 200 watts for now.

my 2 cents worth

I guess it isn't only me and my setup. My AT-600 is not consistent in tuning my antenna, a G5RV. I also bought the AT-600 in order to use a 500 watt amp. I rehooked up my AT-200 and everything works perfectly. Fast tuning and all. There must be a difference somewhere.

Dwayne,

I'm very excited about the remote tuner!! I hope to see an RT-600 and RT-1000 in the lineup also. The reliability of the MFJ tuners and cost of the SGC tuners keep me away. I currently have three LDG tuners (AT-100ProII, AT-600Pro, and Z-11ProII) and I haven't seen a better product for the price.

I've been patiently hoping for a remote tuner from LDG, so this is really good news!

Just a follow-up in case someone else goes to search for this article... it is March 1994 issue, and not the May 1994.

Brad:

Thanks for straightening me out!

Wow! This brings back memories. I beg indulgence for misdirecting people to May 1994, and trust they had enough smarts to check for G5RV for the entire year of 1994 when May 1994 came up with zilch.

This again reminds me that the advice of my pappy (then W?HZP, now sk) to use 135' or so flat top length and 450 ohm (nominal) feed line works like a charm, especially after experimentally determining the best length for the easiest matching on all bands.

And, it reminds me why I had such a $#%^%&# time on 80 meters when I borrowed a station to use during the CQ WPX CW contest and the felllow had a G5RV fed with a random length of 50 ohm coax for use on 80 and 40 meters. Best I could do with the LDG Z-100 was about SWR=3, which didn't bother me, because my rig was rated at 100 watts out and I had turned it down to 5 watts, but.....

And, why one of my friends was having such a $#%^%&# time getting the antenna to work (on 80/75 meters, in particular) until he "tamed it" with 70+ feet of (rather lossy) RG-58u. The losses in the coax caused the rig to look at some impedance which was "reasonable" for his matching device.

My best wishes to those who actually find that a 102' flat top antenna, fed with a specific length of 450 ohm balanced line, and fed directly with 50 ohm coax (without a device to minimize currents on the outside of the outer conductor) is the best thing since sliced bread. One of these daze I'll run across one of you and you can tell me how you are overcoming several laws of physics.

72/73 de n8xx Hg
QRP >99.44% of the time

p.s. You probably can determine that this type of antenna is NOT my favorite.

Topic: 6368 Message: 6368

We've finished the compatibility tests with the IC-7100 and found all current LDG tuners work correctly. The IC-7100 seems to be just like the other recent AH-4 compatible radios from Icom (7000, 7200, 7600, etc).

Group.....

I have the same results as Randy N2RRR. Pro200II works great, Pro600II retunes everytime and comes up with different each time. Cant use new amp until solution is found.

Tom Carroll, W9CSX

In a message dated 7/28/2013 4:14:24 P.M. US Eastern Daylight Time, n2rrr@...t writes:

I too am having the same issue. I bought a AT-600ProII and have an older AT-200Pro. If these were the same design only with beefed up parts in the why can't the 600ProII tune?

Should have done more research before I bought it. Starting to lose my faith in LDG.

I have since reconnected my Pro-200 and it tunes all bands on my Butternut HF-10V (9V with 160 meter coil).

I bought the Pro 600 since I am trying a 600 Watt amp. Have to keep the amp around 200 watts for now.

my 2 cents worth

I use an LDG AT-600Pro with an AL-811. By chance,(dumb luck) I found that the tuner is much happier if I put the amp on standby and tune with 10 watts or so when I change bands. It then behaves much more nicely when I change frequencies within a band.

Topic: 6249 Message: 6373

From Page 3 of the AT600 PRO manual (or, no "dumb luck" needed)

Operating instructions (minimal for those who don't read the manual)
Step#:
5. Bypass the amplifier.
8. When the tuning cycle completes, activate the amplifier, and you're ready to operate!
Note: With the amplifier active, it is suggested to place the AT-600ProII in semi-automatic tuning mode to avoid re-tuning at high power levels.

If you check the manual of the AT600 it tells you to do it that way.

Subject: [LDG-auto-tuners] Re: Bypass and Ant 2 LED

I use an LDG AT-600Pro with an AL-811. By chance,(dumb luck) I found that the tuner is much happier if I put the amp on standby and tune with 10 watts or so when I change bands. It then behaves much more nicely when I change frequencies within a band.

Topic: 6249 Message: 6375

I have an AT-100 Pro II and have never been able to get it to work. Tried using both the LDG 4:1 and 1:1 Baluns with no luck. I was also told it was a grounding problem so I added more ground rods, tied them together and still no luck.

I have an old G5RV that the auto tuner in my Kenwood TS-440 tunes up but the LDG will not.

Right now the LDG tuner is a paper weight in my shack until I decide what I am finally going to do with it.

I understand your problem.

Hi Walt,

You can likely eliminate the issue with two steps:

1. Use as really heavy ground braid that is as
wide or wider than the wing nut (see page 8 in
the following .PDF document
http://www.n2ckh.com/MARS_ALE_FORUM/AT200PC.pdf)
and thick from the ATU directly to the closest
station ground rod or bus if the bus so heavily
grounded. I use braid by Electric Motion Co. Inc.
(EMC) of Connecticut, their part number EM2051
Ultrabond #6, W/WEB
(http://www.electricmotioncompany.com/emc.php?type=bonding&sub=Ultrabond)
which is UL listed and available in 25 foot rolls
and larger. This cable has a safety shock
covering and press fit eyelets the length of the
cable which make attaching to surge suppressors,
grounding studs etc. real nice and secure, a
little ☐Penetrox A ☐ on all connections and
proper maintenance, your antenna will perform flawlessly for a very longtime.

2. Wrap 6 or more turns of the coax cable from
the antenna or jumper cable from the switch box
connecting to the ATU antenna in port around a
large Amidon type 77 core and secure the cable to
the core with nylon ties for a common mode choke.

In the past I used what is today called a G5RV
antenna years ago, most commercial brands do a
very poor job to an awful job of decoupling the
coax and then too the coax commercial units use
is often made with a poor braid. I had issues
with them and my tuners as well, the above two
steps made the issues go away. As a matter of
fact each and every MARS member where with ALE a
lot of use of automatic tuners are made, that has
told me of similar issues that have followed
those two steps eliminated their problem with various broadband antenna types.

73

True. I am one of those folks who can read a manual and a couple of days later, the info is gone. However, when I "discover" something, it usually sticks. That "discovery" is probably the information retrieval from reading finally kicking in. ;)

Travis, I'm glad your problem is solved. "Discovery" learning can be a good thing, but in ham radio it can also be expensive or even fatal. Those manual instructions could read like this: "NEVER apply drive to an amp without first checking the antenna's SWR." Applying power with a high SWR stresses the amp and tuner and is a good way to damage/destroy both, not to mention the unnecessary QRM. If you run an amp through a manual tuner before attending to the SWR issues you run the risk of getting an arc light show and/or pitted/burned tuning caps in the tuner, not to mention the potential for damage to the amp's tank circuit. Solid state gear runs the same risks of damage which is the reason for load fault circuits, etc. It's about voltages.

Sounds like we have some of the same experiences with manuals and learning. I keep mine by the new gear until I've "learned", which sometimes takes a while!!! If only the modern gear were as simple as my Viking Adventurer back in my Novice days!!!

Anyway, glad you got it working. I hope to meet you on the air sometime.

Topic: 6249 Message: 6379

My radio that I use on the amp most of the time is a TS-480sat. I have the PF button set for a 10 watt, CW tuning tone.
I have experimented with a Flex-1500 and FT-817nd with the amp.
Output with five watts drive is about 60 watts.
For the Flex, I had to get a DB-9 cable to make the amp keying cable. (according to instructions from the Flex Folks).
LFH tuners I use are Z-817, Z-11 ProII, and AT-600Pro. Also recently acquired a Dentron Super-Tuner.
By the way, I keep pdf copies of the manuals on my desk-top and open the one for the AL-811 whenever I use it.

Thanks Steve. I have implemented #1 already and saw some improvement but will try #2.

I have a FT-897 and TS-440. I would like to dedicate my 440 to 40m nets and bought the AT-100 for that purpose. I would really like to realize my intention and hope this will help.

I will let you know.

6381. Question about different models

Yahoo group: LDG-auto-tuners (2010 — 2017)

From: kd2cjj
Topic: 6381 Message: 6381

Today I have a AT 100 PRO II... It tunes my mini beam perfectly.. (for the portions of the bands that are not resonant)..

I am considering adding an amp thus need a tuner that can handle more power.

I see when I look at the tuner comparison table that the AT 1000 PRO II has a narrower range of impedance matching. Should I be concerned that I may not be able to tune my antenna anymore? Do you have any advice in what research I can do to ensure that the tuner can handle the tune?

Current at the ends of 20 meter band(CW and Digigal) its as high as a 9:1... the current tuner tunes to a 1:1 within a second or two... (in the ssb portion its below a 3:1; and within the General portion of SSB its below a 2:1)

Thanks for the advice...

I created an external battery pack for my Z-11 Pro II Tuner. I have posted photos of my external battery pack in the photos section under "N2LRB Z 11 Pro II External Battery"

I did not dare play around with the insides of the tuner (soldering) for fear of making a mistake and forever breaking my new LDG tuner. So I purchase an 8 battery (its two sided but you can not tell that from the photos) pack from Radio Shack, added power poles and had a nice external source of power (light weight too) for my tuner. I purchased my tuner for portable HF use.

Steve,
I was about to say, look for a problem in the control cable. I have a KT-100 tuner, and I thought I would be smart and install a hefty RFI filter in the middle of the long control cable I built, and I had similar symptoms. The RFI filter had a PI filter in each of the control and power lines. When I took out the RFI filter the tuner worked like it says in the manual. I made the long control cable out of CAT-5e network cable, paying careful attention to the pairing of the signal wires: four twisted pairs each consisting of a solid and strip colored wire, all the striped wires go to ground and the solids are TT=BRN; TS=ORG; +12VDC=BLU+GRN.
Finally, I made a common-mode (or current-mode) choke by winding the CAT-5e cable on an FT-240-31 ferrite toroid core, and the tuner still works fine.
Glad you got your problem solved so quickly!
73,
Avery, WB4RTP

Have you tried to force a full tune?
Have you tired to manually tune the antenna using the L or C buttons?
Have you tried changing the threshold to see higher or lower helps during an autotune?

The auto tuner is not perfect... On fact my mini beam changes Swr as I rotate it due it's proximity to the house... With that said I have to use many tricks with the auto tuner to get a 1:1 n the radio and on the tuner... I typically let the auto tune happen...it will end up just below the threshold... Then I use the l or c buttons to fine tune it and the store that setting....

Generally make sure the unit is grounded,water pipe is fine, and use a choke on your feedline, tune with no more than 20 watts. Lastly after a tune is set put it into semi auto mde...this will ensure the tuner doesn't start to retune when you apply power. If Swr I creases then just add or subtract L or C...that's why those buttons are there...

I still have an AT-200, so I connected it and it tunes everything as it should. Maybe time to send the AT-600 in for testing.

I don't have the engineering skills to develop this so I am making a request.

Most brands of radios have different methods of interfacing with an external tuner. Why cant LDG create an external rib box that can interface with ALL LDG tuners that can translate the needs of ANY radio? Its frustrating that my current generic LDG tuner AT 100 PRO II interfaces with my older ICOM radio but not my new FTDX3000. I would not mind spending as an option a rib box / cable that could interface between my radio and tuner. Yes I got spoiled with the integration between the Icom and LDG tuner and I want to be continually spoiled as I change radios... I am considering now to upgrade to a 1KW tuner and now at a cross roads... I should not haveto change manufacturers of tuners (yes I have actually considered going to Mighty Fine Junk to get back that seamless integration) OR buy a special LDG Tuner (which they dont have actually but other Yaesu models they hve special tuners - thats nuts!) to get this capability... This would not only make the customer happy but improve your margins lowering your number of products in your catalog...

I also want self up-gradable firmware updates... In today's age this is commodity for most products... even the other guy can do this... I know there must be improvement of tuning algorithms thus want to apply those updates as they come out.. I see many complaints here about the AT 600 PRO II that surely could be resolved with firmware updates..

I don't mind paying a little more to get these features...

LDG you listening?

David--
One thing is certain-- you don't understand the problem. There is nothing needed IN THE TUNER to make this happen. All the various interfaces only make things happen in the Radio.

All the tuner needs is an RF signal to do its thing; The various interfaces just change the radio to make it do the right thing. Radios, in todays market, have great variation in operation. LDG has taken advantage of this market to provide control of some radios.

Most of the time, the following sequence is done.

1. Set the radio to a reduced power level, using a CAT command. Remember where you were, using a CAT Query.
2. Put the radio into a mode that allows a continuous carrier.(eg, CW, AM, or tone modulated SSB), using CAT commands. Remember where you were, using a CAT query.
3. Turn on the Carrier, using CAT command.
4. Measure the outgoing and reflected signals at the Antenna port.
5. Calculate the equivalent to SWR and compare the value to a desired value.
6. Using a proprietary Algorithm, Make tuner changes and repeat step 5 until happy.
7. Using CAT command, Turn the carrier off.
8. Using CAT commands, reset the Mode and power levels to original values.
9. Stand by for normal operation, being ready to do steps 4, 5, and 6 continuously.

Please note how many of these steps require communication with the radio, and reflect on how many different sets of commands there are across the many brands and models there are in the market. There is NO standard.

You need to talk to the radio manufacturers, not LDG. Meanwhile, have the grace to thank LDG for every special adaptation they make available.

David,

I might not have been clear in what I want.

I want to be able to use the Tune button on my radio to perform all operations, not the other way around.

Each radio implements various ways to initiate a tune once those CAT commands have execute. As an example the IC7000 radio does not use CAT to initiate a tune to the tuner where the FTDX3000 DOES issue CAT commands to the tuner as part of the tuning process.

The fact that each radio may have different CAT commands is a simple problem for most software implementations. You can easily abstract CAT commands to internal tuner commands. You may not be able to auto sense what radio is connected but you could through dip switches force profiles for each radio. I attempted to build a wire from my FTDX3000 to my current LDG and found that it was a mute point as my radio needs an intelligent tuner that can decipher the CAT commands issued to the tuner which tells the tuner to trigger a tune. The fact that there is not standard for CAT isnt the obstacle; understanding each radios commands maybe that obstacle, but most are published. You dont have to release EVERY radio either. You can through firmware updates add those commands as needed/found. Furthermore, you really dont need to interface with the radio as you described (though some tuners do). You can keep the tuner very decoupled from the radio and only do the minimum needed to initiate and sustain the tune. There could be a reason why it cant be done but no offence the argument you posed doesnt hold weight with me. Unfortunately I am not an electrical engineer so I am not schooled on how the physical implementation can be done but from the software side I am very confident it can be done.

Michael-- Sorry I got the name wrong.
I still think you don't understand. In my post, only steps 4,5, &6 are done by the Tuner, but they are done WHENEVER there is a carrier. The other steps are only a matter of convenience.
Just what actions do you want when you push "Tune"? Which ones are not being done now? Why doesn't your radio do it?
Be specific.

Subject: [LDG-auto-tuners] Re: Product Request

David,

I might not have been clear in what I want.

I want to be able to use the Tune button on my radio to perform all operations, not the other way around.

Each radio implements various ways to initiate a tune once those CAT commands have execute. As an example the IC7000 radio does not use CAT to initiate a tune to the tuner where the FTDX3000 DOES issue CAT commands to the tuner as part of the tuning process.

The fact that each radio may have different CAT commands is a simple problem for most software implementations. You can easily abstract CAT commands to internal tuner commands. You may not be able to auto sense what radio is connected but you could through dip switches force profiles for each radio. I attempted to build a wire from my FTDX3000 to my current LDG and found that it was a mute point as my radio needs an intelligent tuner that can decipher the CAT commands issued to the tuner which tells the tuner to trigger a tune. The fact that there is not standard for CAT isnt the obstacle; understanding each radios commands maybe that obstacle, but most are published. You dont have to release EVERY radio either. You can through firmware updates add those commands as needed/found. Furthermore, you really dont need to interface with the radio as you described (though some tuners do). You can keep the tuner very decoupled from the radio and only do the minimum needed to initiate and sustain the tune. There could be a reason why it cant be done but no offence the argument you posed doesnt hold weight with me. Unfortunately I am not an electrical engineer so I am not schooled on how the physical implementation can be done but from the software side I am very confident it can be done.

Michael--
I just went back and read your last post again, and I am puzzled. I will read the CAT manual for the FTDX3000 and see what command "Triggers" a Tune cycle (in a non-Yaesu Tuner).
As a matter of fact, which LDG tuner requires a CAT signal to initiate a tune cycle?

Michael--
You keep mentioning your ICOM--
Which model Icom, and which tuner?
And- can you tell me what actions happened, in sequence, when you pressed the "Tune" button on the Icom?
You have me interested, now, even if still in the dark, as far as details go.

I too would be interested in interfacing multiple radios to one tuner so that each radio's "tune" button works.
I'm sure CAT is not the "only" way. Frequency sensing circuits are used in many devices now.
Interestingly, my Icom IC7600 internal tuner menu has a setting that will tune on PTT in ANY mode where it senses the SWR to be too high.
It must be possible, but at what cost?
I imagine it's easy with carrier based modes. but what about SSB. Does the tuner need to have a 10 watt frequency agile HF transmitter embedded(as it could), together with frequency sensing circuit.
If Byonics can sell an APRS tracker plus 10 watt VHF FM transceiver for $US220, anything is possible !
(Now I wish I could patent the idea....)

You can keep the tuner very decoupled from the radio and only do the minimum needed to initiate and sustain the tune. There could be a reason why it cant be done but no offence the argument you posed doesnt hold weight with me. Unfortunately I am not an electrical engineer so I am not schooled on how the physical implementation can be done but from the software side I am very confident it can be done.

You can buy plastic "ammo" boxes about anywhere;Walmart,Farm & Fleet etc.
They have a gasket in the lid..drill holes for the radial wire and the vert wire,put a bulkhead/barrel connector 239 in it and the tuner inside.
I have one thats been outside for years in a waterproof box bought at Farm & Fleet for $12.
Mine has power fed through a pair of MFJ BiasT's. Somewhere in the photos section of the S9antennas group I believe there are pics of it under my old call KB0NAZ

So I purchase an 8 battery (its two sided but you can not tell that from the photos) pack from Radio Shack, added power poles and had a nice external source of power (light weight too) for my tuner. I purchased my tuner for portable HF use.

Is the LDG100z plus usable as a random wire tuner? The instructions suggest it's for any coax-fed unbalanced antenna...

Also, if yes, is a balun really needed? (and if so, why?)

6400. Still haven't gotten any help on this matter!!!

Has anyone made the horrible mistake of, during the factory default reset procedure, briefly applying power to the radio connector on the back?
I do not use the radio connection, however since the above action occurred, the tuner does not tune. All the LEDs light up left to right, then all Flash.
I opened the cover and found no evidence of anything burnt.

Any help would be greatly appreciated... looking for schematics too.

Thanks and 7 3

I would say that you need to send your tuner for repair. If you applied power to the radio connector I am sure you have burnt something up. I am not aware of any reset procedure for the LDG line of tuners.

Why knot? All it is is an impedance matching device. Be sure to use
some sort of counterpoise or earth ground.

A Balun is definitely NOT needed, but an RF choke, or sometimes called
and UN-UN is sometimes beneficial to reduce currents which may be
induced from the near fiedl of the antenna - sometime it's best to have
two of these devices, one very near the tuner to for your random wire,
and the other at the transceiver end.

Hello KD0UCR,

When you have random input for data, you end up with a random answer. Most of the LDG tuners have a tuning range of 10:1. So you would need to know the impedance of the random wire to be able to provide an answer. There is no way to even know if you need a balun or not.

Depending on what radio you have, there may be other tuners (more expensive) that will work with your random antenna.

6405. Delay of the AL-100

From: Dwayne
Topic: 6405 Message: 6405

Due to several unforeseen circumstances, the AL-100 will most likely be shipping in Sept. We originally expected delivery in June, but delay after delay has pushed it past that.

Normally, we do not even announce a new product until we have it in our production line, but we mistakenly thought this one would be easy to get through.

We apologize for all of the delays and promise to ship as soon as possible.

I homebrewed a 4:1 / 1:1 current balun in a single small plastic box. I have external banana plugs to select 1:1 or 4:1. I generally use the 4:1 for a random wire, but on a few occasions I needed to switch to the 1:1 to get me Z-817 to match.

Your other choice is to add 2 to 5 feet of wire to the random wire or to the counterpoise. This will change the input impedance.

From: E
Topic: 6389 Message: 6408

I did some extensive work with auto tuners and the FT-950.
There are a few issues that would need to be addressed in order to have a "universal interface capable" tuner.

1) The interface voltage levels would need to be programmable.

2) The protocol used might be as simple as level shifting or as complex as commands with expected responses - both approaches, and every protocol used would need to be handled.

3) And here is the kicker... some "Tune" sequences, such as the FT-950 tune sequence, will only get past the first its' first RF output test IF the SWR is approx 3:1 or lower. The only way to guarantee this is to provide an antenna load in the tuner itself which would be in the antenna path (instead of the actual antenna) for the first RF output test and then switch out of the antenna path for the actual tuning sequence. This is why the AT-200 Pro I have will not work properly with the FT-950's "tune" button.

There was a Yaesu interface device sold which would translate the CAT command sequence into the level shifting sequence that ICOM used (uses?) but without being able to limit the initial SWR results to 3:1 or lower, the device only worked when the antenna was already close to being tuned before the tuning started.

All that being said, a modular tuner with a "base unit" that included a loading resistor and relays to switch it into/out of the RF path as well as the RC tuning components, the forward and reverse power measurement sensing and the smarts to determine an acceptable LC configuration should be possible to build and could be coupled to a interface specific front end, but the result may be more complex and therefore more expensive than most everyone would actually need for any given radio.

> >
> > The fact that each radio may have different CAT commands is a simple problem for most software implementations. You can easily abstract CAT commands to internal tuner commands. You may not be able to auto sense what radio is connected but you could through dip switches force profiles for each radio. I attempted to build a wire from my FTDX3000 to my current LDG and found that it was a mute point as my radio needs an intelligent tuner that can decipher the CAT commands issued to the tuner which tells the tuner to trigger a tune. The fact that there is not standard for CAT isnt the obstacle; understanding each radios commands maybe that obstacle, but most are published. You dont have to release EVERY radio either. You can through firmware updates add those commands as needed/found. Furthermore, you really dont need to interface with the radio as you described (though some tuners do). You can keep the tuner very decoupled from the radio and only do the minimum needed to initiate and sustain the tune. There could be a reason why it cant be done but no offence the argument you posed doesnt hold weight with me. 6409. AT 200 Pro

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2013-08-13 09:03:05 UTC
From: John
Topic: 6409 Message: 6409

Guys,
Newbie here!
New to Auto Antenna Matching at least!
I recently bought a used AT200 Pro, seems to work fine, to my limited knowledge at least!
An odd problem has popped up . . . .
While tuning up on 28 MHz recently, all worked ok.
Then without changing frequency, I keyed up again . . . . . the AT 200 went back through a full cycle!!!! - It does tune up OK, but it insists on retuning every time I key up . . .
I thought the unit remembered settings ??
Have I a faulty unit or am I missing something here . . . ???

Oh, BTW, the antenna is a 102' doublet fed with about 15M of 300 ohm ladder, 4:1 balun, short length of mini8
It shows about 280 ohms Z at 28.5 Mhz, untuned . . . . . .

TIA & 73'

6410. Z-11 Pro II Tuning Question

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2013-08-13 22:12:53 UTC
From: n2lrb@...
Topic: 6410 Message: 6410

While using my Z-11 Pro II tuner out of doors in Central Park, I decided to lower the wattage of my Yaesu FT-857D transceiver to 10 watts and change the mode to AM every time I switched bands. The tuner and the radio are connected via the radio's ACC port using the special cable I purchased for that purpose.

My question is this. Was I right in lower the power before putting the radio on AM to tune or does the tuner lower the power and put the radio on AM automatically for me (though I may not see it happen) while tuning?

Jose

From: Hank Greeb
Topic: 6410 Message: 6411

Hi, Jose:

It's always best to tune with lower power. And,if the Z-11 is like my Z-100, 5 to 10 watts is a nice power for the circuitry inside the unit to work. The Z-11 doesn't control the radio, whatever the "tune" buttondoes to the radio iswhat happens when you push the "tune" button on your radio.

Unless it is specified in the 857 manual that the poweris reduced when you press the "tune" button, manually lowering the power to 5 to 10 watts prior to pushing the tune button is a prudent thing to do.

72/73 de n8xx Hg
QRP >99.44% of the time

p.s. my "problem" with my Z-100 is that Ioften have toINCREASE power from <1watt to around 3 to 5 watts in order to allow the circuits to work properly. :)

You weren't wrong but it really isn't necessary. The 857 has fold back
and will reduce power as SWR goes up.

The TXRQ line that the tuner hooks to on the 857 doesn't affect power
output of the radio so you would have to manually lower the power if you
are concerned with the fold back circuits operation.

From: kd2cjj
Topic: 6389 Message: 6414

When I press the tune button on the Icom it lowers the power to 10 watts, it changes the mode to CW then sends a carrier to trigger a tune. The tuner finds a match and the radio go back to which ever mode you were on.

I want this type of function for any radio. All steps above with my Yaesu are manual... (Lower power, change mode, send carrier, - tuner kicks in -- then switch mode back, raise power)

Tom,

This is a common problem. Oh and yes, I realize that my answer was no help. I think you just have to accept that the 600Pro/ProII will not necessarily tune the same things that the 100 & 200 Pro/ProII will.

>
> I purchased a 600 Pro II to use on the same setup with a amplifier in the future. It tunes OK on 40, 15 and 17 but not as low a SWR as the 200 Pro II. But it will not lock up on 20 and shows a SWR above 1:7 or above 2:0. I TX LDG but did not get my problem solved to my satisfaction. They suggested setting the SWR threshold higher than 1.7. I set it to 2.0 and higher with no better results. I switch back to my 200 Pro II and its 1.3 or better right away.

Have you tried manually tuning. Get a match with the auto tuner as good as it will get... then hit the L up or down. Watch the SWR. Keep hitting up or down until it wont go lower.. then hit the C button up or down until it gets to the lowest SWR. Then you can hit Func. Store to store that setting. I know you should not have to do this but even on my AT100PRO II I have to do this some times. The threshold will help, but it may not. If all else fails add or remove 5 - 7 feet of feedline. A little bit could make the difference.

E--
I think your comments belong somewhere else, because much of what you say does not apply to LDG tuners, which is the focus of this group. Your #3 was the first, obvious miss-fit. The 3:1 SWR problem is true of the Yaesu internal tuner, but not many other, external tuners, such as the LDG line.
Bill--W4BSG

Subject: [LDG-auto-tuners] Re: Product Request

I did some extensive work with auto tuners and the FT-950.
There are a few issues that would need to be addressed in order to have a "universal interface capable" tuner.

1) The interface voltage levels would need to be programmable.

2) The protocol used might be as simple as level shifting or as complex as commands with expected responses - both approaches, and every protocol used would need to be handled.

3) And here is the kicker... some "Tune" sequences, such as the FT-950 tune sequence, will only get past the first its' first RF output test IF the SWR is approx 3:1 or lower. The only way to guarantee this is to provide an antenna load in the tuner itself which would be in the antenna path (instead of the actual antenna) for the first RF output test and then switch out of the antenna path for the actual tuning sequence. This is why the AT-200 Pro I have will not work properly with the FT-950's "tune" button.

There was a Yaesu interface device sold which would translate the CAT command sequence into the level shifting sequence that ICOM used (uses?) but without being able to limit the initial SWR results to 3:1 or lower, the device only worked when the antenna was already close to being tuned before the tuning started.

All that being said, a modular tuner with a "base unit" that included a loading resistor and relays to switch it into/out of the RF path as well as the RC tuning components, the forward and reverse power measurement sensing and the smarts to determine an acceptable LC configuration should be possible to build and could be coupled to a interface specific front end, but the result may be more complex and therefore more expensive than most everyone would actually need for any given radio.

A basic understanding of SWR seems to be the issue with what a tuner can and can not adjust to.

<http://www.moonraker.com.au/techni/smith.jpg>

This is a "Constant SWR circle" on a Smith Chart. The values corresponding to an SWR of 3:1 are on the edge of the circle.
Note that ONLY TWO places on the circle are resistive. 0.33 and 3.0 on the horizontal flat line across the center of the chart.

All other points have a combination of a real (resistive) part and a imaginary (reactive) part being either inductive or capacitive.

Most "modern" transceivers with a built in antenna tuner claim to be able to adjust up to a 3:1 SWR.
Most "modern" stand-alone antenna tuners claim to be able to adjust up to a 10:1 SWR.

When you consider the near infinite range of variables to be compensated for it's amazing that an antenna tuner can do the job as well as it does.

If you have a basic understanding of how a Smith Chart works, you can see how adding or subtracting a length of antenna feed line will affect what the tuner has to compensate. Also, proper selection of a Balun or Un-un to put the antenna into a range the tuner can compensate for is equally important.

Contrary to popular belief, antenna tuners typically will NOT adjust "Anything from my wife's panties to the neighbors chain link fence."

6419. SWR Reading on Radio VS on LDG Tuner

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2013-08-17 03:38:13 UTC
From: kd2cjj
Topic: 6419 Message: 6419

I have noticed this since the day I got my AT100PROII and now on my AT1000PROII.... Why for some frequencies within a band does the radio show a much higher SWR vs what is on the tuner? Is there anything I can do to lower the SWR on the radio other than tuning the tuner? I have confirmed that it is not my radio since the SWR meter reads what my radio is reading. Now this is two tuners doing this..

Thanks

I personally use outboard swr/wattmeters (Diawa & Palstar) and go with whatever they say.

It depends where you out the tuner, before or after the tuner.

If I put my external meter before the tuner it matches the radio Swr reading. If I put it after the tuner it of course shows the real Swr.

The point I am getting at is why is the tuners Swr so off from anything before the tuner only sometimes. Other times its close or right on.

As an example I could be showing a 1:1 on the ldg and a 2:1 on the radio. That's a big difference. It's not the radio's meter because it shows what my external meter reads.

This poses an issue because the tuner thinks everything is fine meanwhile the radio is folding back. It won't tune down... Some times even if I manually tune using the buttons the tune shows a 1:1 but the radio and meter won't go lower than a 1.8:1 or even worse.

I have tried different cables, putting ferrites on the feed lines, etc. no help... What gives?

This goes back to the problem of RF getting into the tuner. And it doesn't HAVE to get in via the DC power cable, or the antenna cables.
ANY RF getting into the detector from anything other than the true reflected RF is going to adversely affect the readings. It also causes
the tuner to retune when it should be just fine.

This is why I repeatedly tell people "Buy a hand full of ferrite chokes and experiment. Because you'll be surprised where one WILL make a difference."

As an example, I needed one on the 6' USB cable to the printer. At the PC end of the cable. That shouldn't have made ANY difference, but it did.

I noticed with my Z-11 (original) that the internal SWR metering on the FT-817 was not showing minimum when the the Z-11 finished tuning. I can get significantly more power out of the 817 when I use the CAP and IND up/down switches on the Z-11 to minimize the SWR as seen by the 817. I assumed that this was a problem with the calibration of the LDG, and I got a helpful reply when I wrote to LDG tech support for guidance in how to adjust the Z-11 internally. It has been my intention to do this with a good dummy load, but I haven't done so yet, and I realized I should also try to find out if there is a way to calibrate the SWR sensing circuits in the transceiver.

In the end, however, I expect I will go with whatever makes the QRP transceiver happiest, since it will actively reduce power output if it doesn't like the SWR it senses.

I also have a Z-100Plus that I use with an Alinco DX-70 for QRO operation. The Z-100 doesn't have provision for adjusting its L and C manually, and the DX-70 doesn't indicate sensed SWR, so I'm not sure whether I have problems with this combo.

All that said, I had not considered that r.f. could be getting into the tuner as suggested by WA6FWI. For both of my setups I use very short coax from transceiver to tuner and the 12 V supply lines are also Y-connected very close to both units.

You might try the z-817 tuner as it is designed specifically for the FT-817 and will give a great match.

I did some experimenting with my new AT1000 PRO II (also have a 100PRO II that is being replaced).

What I have noticed is that some times it does NOT actually find the best match. Some times its on the fringe and incorrectly selects the wrong Hi/LoZ. Under the circumstances that this happens I noticed that the SWRs are not matching the radio, by a significant amount...

I will do a comparison between the my AT PRO II 100 vs 1000 to give the rest of my findings in a different thread. With that said, there is surely something afoot. Can LDG chime in on this issue?

6426. Impression of LDG AT 1000 PRO II vs LDG AT 100 PRO II

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2013-08-18 00:14:38 UTC
From: kd2cjj
Topic: 6426 Message: 6426

I just upgraded to the 1000 coming from a 100 in anticipating of getting an amp. I have a TGM MQ26 Mini beam antenna which has about 100 Khz of bandwidth (<2:1 SWR). At resonance the antenna is 1.3 which is set to 14.265. I have a Yaesu FTDX 3000. Feedline is LMR400 Flex about 45 feet (roughly).

Here are my observations:

Size: Its massive. Easily twice the size over all.

Noise: It scared me the firt time it tune! LOL. I thought it was going to explode. The 100 is noisy but the 1000 fogetabowit!
Speed to Tune: A little slower for the band edges where I have a 9:1 SWR. Towards resonance part of the band its the same. And pulling from a memory slot is just about the same.

Bandwidth of the Tuner: With T networks you have virtually no bandwidth. In other words once you leave where you have tuned you need to retune. L Network based tuners you have a very wide bandwidth due to the nature of the tuners Network. Anyway, the 1000 has significant improvement on bandwidth. My 100 has about 60Khz on a non-resonant portion of the band. With the 1000 I have about 125Khz before a tune needs to happen. I am very happy about this!

Efficiency: I can seeing more power leave the tuner. I generally would average around 75 watts leaving the tuner; I am now seeing close to 80 and 90 watts average. This is not scientific as I am only comparing using my power meter. But I am seeing an improvement.

Matching: The AT 100 PRO II tuned everything I through at it EXCEPT 1 frequency 14.346. I would get a 3:1 SWR. I could NEVER tune that frequency for some reason on the 100. The same on the 1000. It could not tune it. And the kicker was I could not tune either at the low end either.. I lost the ability to get a good match (less than 2:1) on frequencies like 14.070. I like to work digital so I was very upset. On the 100 it tunes to a 1:1. On the 1000 it was about a 2:1 on my radio and it said 1.7:1 on the tuner. In either case my radio was folding back. It was usable but still not happy. I have become a blackbelt at using the LDG tuners; I tried using all the manual settings and to no avail. I also added and removed feedline length. Didnt help. I started to clean my office and I found a Balun Designs high power 1:1 balun that I had used on an old dipole - this one had SO239s on each end. I decided to give it a shot and put it in line... Amazing!!! I got a 1:1. And the 14.346 which I could not tune before it tuned to a 1.3:1! I suspect there is loss being added thus lowering the SWR BUT my power meter is reading the same. I did many tests with and without and saw no difference in my signal reports. I am now wondering if I had common mode (even small amounts) that were getting into the tuner? Could this tuner be more suseptable? Can anyone shed light on this? If anyone else has a similar balun can you try this if your having an issue with tuning? Keep in mind this is not a simple ferrite over coax balun. It is a high performance guanella balun. Any feedback appreciated..

I dont have my amp yet (its my first). I will post back my experience when I get it.

The station here: Icom IC-761. 12" Jumper RG-214 to Kenwood SM-220. 18" Jumper to LDG Z11 Pro II. 12" Jumper to 9:1 Balun. 35' 450 Ohm window line to 102' doublet inverted-V. Behind the station I have an 8' L-shaped piece of 3/4" copper pipe with 12" #10 AWG jumpers to tie all the equipment to ground. Including the PC and tuner, etc..
And #4 AWG from the station ground, to the earth ground and tower bond to ground.

Despite that, I have several Ferrite snap on cores in various places to make the entire package act civilized.

Preliminary information has been posted to the LDG web site. We even have a preliminary manual. The expected ship date is in September 2013. As you may have seen, we have already been field testing the first prototypes.

Unfortunately, the AL-100 has had the most production delays of just about any project that we have ever done. The new ship date is also September 2013.

We'll keep you posted on any changes.

6430. Fixed my tuning issue when going from AT 100 PRO II to 1000 PRO II

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2013-08-19 14:17:53 UTC
From: kd2cjj
Topic: 6430 Message: 6430

I see some complaints that the 100 can tune anything and the 600 (especially) and 1000 cant tune OR get as low as the 100.

Guess what, When I got my 1000 I had the same issue. I could not tune as low in some areas and I just could not tune within resonance frequencies that went to a 1:1 on the 100. Like the rest of you I was pretty upset. After finding the solution, hands down the 1000 is a better tuner all the way from efficiency to bandwidth (see my other thread).

I experimented in a few places and found MY solution. I cant guarantee that this will fix yours but its worth a try.

The ONLY change I did (after much testing/fooling around) that fixed the issue was adding a guanilla balun (balun designs) in my shack on the antenna side of the tuner (using a 3 foot RG213 jumper from the tuner to balun with LMR400 flex on the antenna side of the balun). I can now get a 1:1 on just about the entire band (a few areas where it wont tune, even using the manual buttons, better than a 1.5:1). On frequencies that refuse to get below a 2.5:1 (even using manual tuning) now are no more than 1.5:1. Frequencies that were a 2:1 are now 1:1. I suspect that high SWRs coupled with some stray common mode was the culprit. I believe the balun did two things. It not only added some loss it also removed any stray common mode both of which allowing the tuner to become more effective. I tried adding literally 30 feet of coax as one my experiments and that did not help. I say it must be either stray common mode or a little bit of loss plus common mode. Adding loss did NOT fix the issue.

I have validated that the loss added is not measurable by my cheap watt meter (it see no difference on put) and my audio reports are no worse. What I do see now is my transceiver for those frequencies that were a 2:1 is not folding back and putting out full power. And frequencies not tuneable below a 2.5:1, well they are now usable and with full power.

Let me know if this works for you!

Sorry.... Fat fingered... Its a Guanilla Balun - different than a simple ferrite slipped over coax. Guanilla baluns offer greater choking impedance over simple ferrites over coax.

Here is the balun I am using:

Max Choking 1:1 Isolation Balun 1 - 54 MHz 5kW - #1115d
http://www.balundesigns.com/servlet/the-63/balun-designs-1-cln-1-Isolation/Detail

The Guanella is a current or choke type balun. I suspect he is using this one.
<http://www.balundesigns.com/servlet/the-101/1-cln-1-Isolation-Balun-/Detail>

I've mentioned this before, and I can't stress this often enough, the importance of a proper Guanella / Choke / Current balun to keep RF off of the shield of the coax connected to the LDG antenna tuners. Although this is not an LDG specific problem, it is germane to just about any feed line situation.

Equally important is the correct matching ratio, 1:1 for 50 ohm to 50 ohm. 4:1 for 200, NOT 450 ohm feed lines and 9:1 for 450 ohm feed lines.

Note: Choke baluns come in even integer values. 1, 2, 3 and 4 for squared values of 1, 4, 9 and 16 to 1.
Other values such as 6:1 baluns (typically 300 ohms to 50 ohms) are either a direct VOLTAGE type balun, or a combination of a 1:1 choke balun feeding a 6:1 voltage balun.

Im using this one:
(i the darn URL just isnt posting propoerly!!!)
http://www.balundesigns.com/servlet/the-63/balun-designs-1-cln-1-Isolati\
on/Detail
<http://www.balundesigns.com/servlet/the-63/balun-designs-1-cln-1-Isolat\
ion/Detail>
I agree.. It must have been a very small amount of common mode..

Also... a few points I would like to add...

I suspect the balun is changing the inductance and/or reactance of the antenna - even in small amounts can make a difference to the tuner and may not have anything to do with stray common mode.

Here is my theory:

I have found LDGs algorithm probably needs some tweaking. It tries to find the best SWR at or below the threshold in the quickest amount of time - this will typically yield a good match but not the best match.

This is flawed since time is a component (I am speculating since I am seeing flaws in the resulting tune - i explain why this is flawed down below). In my mind they should allow the user to set a time threshold of the tune. The recommended one and then up from there. I believe the tuners are NOT permutating through all combinations and only a subset and stopping at a good match and not the best match.

Why do I think their algorithm is flawed? The tuners ability to find a the best match using auto match and finding the best match manually adjusting capacitance and inductance unfortunately dont always yield the same results. In other words, if the tuner cant find a match using the auto tune sequence doesn't mean it generally cant find a match you desire. You need to set the threshold lower than you want to ensure it tunes BELOW that point. If it cant find a match LOWER than the threshold it will fail. As an example if you set the threshold at 1.7 SWR and it finds a 1.8 it will NOT find a tuning point and will continue to try and eventual fail OR find a match but maybe higher than a 2:1. BUT you may have been able to tune using the proper combination of Hi/LoZ, capacitance and inductance manually and achieve a 1:1. If you want the best match then you need to add/subtract capcitance or inductance manually typically unless it finds the best match. Furthermore, If your on the fringe between the Hi or Low Z some times it selects the wrong Z and your SWR may be higher than you want but at the threashold or even higher. As soon as you select the alternate Z it could drop to a 1.8 then add/subtract inductance or capcacitance and you get a 1.0. I have found the frequency that this happens. At that point you need to manually store that match to ensure it goes to that setting immediately rather than retuning or living with a lower match.

The long winded point I am making is that the balun will NOT improve the algorithm it uses. You may get a better match by tweaking the results using the manual buttons (C, L, Hi/LoZ). I still have to sometimes tweak the results of the auto tune even with the balun BUT across the spectrum my matches are quicker and result in lower SWR.

When I get home I will hook up the tuner to my analyzer to see exactly the difference in impedance at a certain frequency.

>
> I see some complaints that the 100 can tune anything and the 600 (especially) and 1000

cant tune OR get as low as the 100.
>
> Guess what, When I got my 1000 I had the same issue. I could not tune as low in some areas and I just could not tune within resonance frequencies that went to a 1:1 on the 100. Like the rest of you I was pretty upset. After finding the solution, hands down the 1000 is a better tuner all the way from efficiency to bandwidth (see my other thread).
>
> I experimented in a few places and found MY solution. I cant guarantee that this will fix yours but its worth a try.
>
> The ONLY change I did (after much testing/fooling around) that fixed the issue was adding a guanilla balun (balun designs) in my shack on the antenna side of the tuner (using a 3 foot RG213 jumper from the tuner to balun with LMR400 flex on the antenna side of the balun). I can now get a 1:1 on just about the entire band (a few areas where it wont tune, even using the manual buttons, better than a 1.5:1). On frequencies that refuse to get below a 2.5:1 (even using manual tuning) now are no more than 1.5:1. Frequencies that were a 2:1 are now 1:1. I suspect that high SWRs coupled with some stray common mode was the culprit. I believe the balun did two things. It not only added some loss it also removed any stray common mode both of which allowing the tuner to become more effective. I tried adding literally 30 feet of coax as one my experiments and that did not help. I say it must be either stray common mode or a little bit of loss plus common mode. Adding loss did NOT fix the issue.
>
> I have validated that the loss added is not measurable by my cheap watt meter (it see no difference on put) and my audio reports are no worse. What I do see now is my transceiver for those frequencies that were a 2:1 is not folding back and putting out full power. And frequencies not tuneable below a 2.5:1, well they are now usable and with full power.

Sorry.... Fat fingered... Its a Guanilla Balun - different than a simple ferrite slipped over coax. Guanilla baluns offer greater choking impedance over simple ferrites over coax.

Here is the balun I am using:

Max Choking 1:1 Isolation Balun 1 - 54 MHz 5kW - #1115d

Mike--
I think you are mistaken in your assumption that the tuner is trying to find the BEST match. I think it is trying to find an acceptable match that is below a threshold set by he user. This acceptable match might be improved upon, manually.
BIG difference.

Subject: [LDG-auto-tuners] Re: Fixed my tuning issue when going from AT 100 PRO II to 1000 PRO II

Also... a few points I would like to add...

I suspect the balun is changing the inductance and/or reactance of the antenna - even in small amounts can make a difference to the tuner and may not have anything to do with stray common mode.

Here is my theory:

I have found LDGs algorithm probably needs some tweaking. It tries to find the best SWR at or below the threshold in the quickest amount of time - this will typically yield a good match but not the best match.

This is flawed since time is a component (I am speculating since I am seeing flaws in the resulting tune - i explain why this is flawed down below). In my mind they should allow the user to set a time threshold of the tune. The recommended one and then up from there. I believe the tuners are NOT permutating through all combinations and only a subset and stopping at a good match and not the best match.

Why do I think their algorithm is flawed? The tuners ability to find a the best match using auto match and finding the best match manually adjusting capacitance and inductance unfortunately dont always yield the same results. In other words, if the tuner cant find a match using the auto tune sequence doesn't mean it generally cant find a match you desire. You need to set the threshold lower than you want to ensure it tunes BELOW that point. If it cant find a match LOWER than the threshold it will fail. As an example if you set the threshold at 1.7 SWR and it finds a 1.8 it will NOT find a tuning point and will continue to try and eventual fail OR find a match but maybe higher than a 2:1. BUT you may have been able to tune using the proper combination of Hi/LoZ, capacitance and inductance manually and

achieve a 1:1. If you want the best match then you need to add/subtract capcitance or inductance manually typically unless it finds the best match. Furthermore, If your on the fringe between the Hi or Low Z some times it selects the wrong Z and your SWR may be higher than you want but at the threashold or even higher. As soon as you select the alternate Z it could drop to a 1.8 then add/subtract inductance or capcacitance and you get a 1.0. I have found the frequency that this happens. At that point you need to manually store that match to ensure it goes to that setting immediately rather than retuning or living with a lower match.

The long winded point I am making is that the balun will NOT improve the algorithm it uses. You may get a better match by tweaking the results using the manual buttons (C, L, Hi/LoZ). I still have to sometimes tweak the results of the auto tune even with the balun BUT across the spectrum my matches are quicker and result in lower SWR.

When I get home I will hook up the tuner to my analyzer to see exactly the difference in impedance at a certain frequency.

No... I believe we are in agreement. Im saying that the tuner tries to find a good match... NOT the best match. I am trying to quell that myth that it tries to find the best match. Again, we are in agreement.

Anyway... I did my test and as I suspected. I was wrong in the original assumption that I had common mode current. And I was shocked with the findings. I knew that a balun would add loss (resistance) but what I didnt factor (but suspected in a later thread) that it was adding reactance to the equation. I was right...

Here is what I found. What do you think?

Dummy Load - 47Ohms Test

BAL NOBAL BAL NOBAL BAL NOBAL BAL NOBAL
14.000 SWR=1.1 1.0 Z=57 50 X=0 3 R=57 47
14.250 SWR=1.1 1.0 Z=57 50 X=0 3 R=57 47

Antenna (TGM MQ26) Mini Beam Test
BAL NOBAL BAL NOBAL BAL NOBAL BAL NOBAL
14.000 SWR=8.2 8.8 Z=99 16 X=93 11 R=15 5
14.250 SWR=1.7 1.7 Z=80 59 X=20 28 R=80 54

No Reactance (resistive) Test

With Balun (could not achieve no reactance, pure resistive)
14.258 SWR=.16 Z=35 X=6 R=32

Without Balun
14.271 SWR 1.3 Z=65 X=0 R=65

Impedance 50 Ohm Test

With Balun
14.274 SWR=1.2 Z=50 X=11 R=49 Phase Angle=0 degrees

Without Balun
14.225 SWR=2.2 Z=50 X=37 R=34 Phase Angle=43 degrees.

Resonance Phase Angle =0 and X=0

With Balun (can not achieve resonance)
14.297 SWR=1.5 Z=30 X=6 R=30 Phase=0 degrees

Without Balun
14.270 SWR=1.2 Z=50 X=0 R=65 Phase=0 degrees

Tom,

Something interesting to note. I recently was experiencing some random tuning issues with the 600Pro due to rain on my ladder line. I was able to get an acceptable match, but figured I could probably fine tune it down closer to an ideal match.

In doing this, I did exactly as you described. I first adjusted for inductance (L) and then capacitance (C). I was only transmitting about 15 watts for JT-65HF. After about the third transmission, I began smelling the tell-tale signs of burning electronics.

I immediately ceased transmitting and started looking for where the smoke was originating. My nose took me to the 600Pro. I pulled it out and opened the case cover. Luckily nothing significant looked burnt, but one of the toroids was so hot it had melted the hot glue that held it in place. I do not see any scorching on the toroid itself, so I have continued to use it....although not until the toroid cooled to room temp.

This wasn't the first time I've had an issue with the toroids though. When I first got the 600Pro, I scorched one to the point that it cracked. This was adjacent to a toroid that just overheated. LDG was kind enough to replace the last one for free. On that first occasion, the SWR meter showed a reasonable match and I hadn't tried to fine tune it further. I honestly don't know why this keeps happening. Maybe the core material is not of the highest quality and/or contains contaminants. Who knows. It does appear that maybe the 600ProII uses larger toroids, because the replacement core was nearly twice the size of the original that smoked.

> Have you tried manually tuning. Get a match with the auto tuner as good as it will get... then hit the L up or down. Watch the SWR. Keep hitting up or down until it wont go lower.. then hit the C button up or down until it gets to the lowest SWR. Then you can hit Func. Store to store that setting. I know you should not have to do this but even on my AT100PRO II I have to do this some times. The threshold will help, but it may not. If all else fails add or remove 5 - 7 feet of feedline. A little bit could make the difference.

I use my Z11 at the base of my vertical. It is mounted in a tupperware type box and the coax is sealed with rubber grommets. The Z11 gets very hot from the sun due to its black paint. I covered the box with aluminum foil and the temp stays normal.
Is there a better way to do this?

I would keep it covered with Aluminum tape. I did this for a router we had 120ft up a tower and it lasted for 7 years. In that case we used a Tuperware box and had it upside down with no bottom on it. It just kept the rain and snow off.

Make sure you keep the bottom open for air flow and to allow water to run out. There is almost no practical way for use to keep things waterproof. What is more important is ensuring that we keep some sort of air flow through it to keep the humidity down.

If you seal the box, you will likely find out that a year from now it is pretty damp inside, especially if you let it heat up and cool and that will ruin your tuner.

Better to let the air and fresh water just flow through it.

Is it better to use a wall power supply or use the same power supply I am using for my rig (32 amp switching power supply)? --- In ldg-auto-tuners@yahoogroups.com, <ldgyahoo@...> wrote: Hi All,

We've had a few people ask about power supplies for the AT-200, 600 and 1000 series tuners. While www.cheapham.com carries a wall mount power supply for the 100 watt tuners, nothing is readily available for the higher powered tuners.

Many people use the same power supply that powers the radio, but not everyone has that choice if the power supply is built in.

After ordering many models and testing for a few weeks, we have chose to recommend a wall mount DC power supply from Jameco (www.jameco.com). The model number is 1953663 and costs about $15. It's 12 volts DC, 1000 mA and has a 2.5 x 5.5 mm, center positive plug on it.

I purchased a cheap 12v 1.75a dc supply from Radio Shack that powers my tuner and several other 12v devices in the shack. I was able to pick it up at a hamfest for $10. Unfortunately, Radio Shack no longer makes RS brand 12v power supplies. If you can find a 22-127 at a hamfest grab it.

If not, check on Amazon.com. You can find a number of supplies for under $20 that will supply 12v at 5a or less. Its great to have a small extra supply in the shack for "future" needs.

Be careful with those RS wall warts. (Actually, ANY wall warts, but ESPECIALLY RS) I bought a brand new RS wall wart to run an MFJ dsp unit. The power connector was miswired, and that fact, in combination with the fact that, even after all these years, MFJ still refuses to spend the mills (1/10 of a cent) to install reverse polarity diodes, the entire dsp board was, quite literally, smoked.

I took it to a commercial techie friend who spent about 10 minutes checking it over. He then turned, took me by the shoulders, shook me and said, in his best Bones McCoy voice, “Damn it, David – IT’S DEAD!!”

Check that polarity before you use it. You may never find a bad one, but the 2nd level of defense is what ever you plug it into.

I have stopped using wall wart supplies whenever possible. The unloaded voltage that the equipment will see when first turned on can exceed the stated voltage rating on the wall wart. I had a Ten Tec wall wart for a 1254 receiver. It was supposed to be 15v but was closer to 20!. Has anyone else noticed this? Get out your VOMs and measure them. You will be surprised and the inrush voltage. I now use my shack supply ---an Astron linear supply. 73 Mike KF6KXG

I should have been clearer. The RS power supply I was referring to is not a wall wart. Its a stand alone unit that has a power cord, a circuit breaker, on/off switch and binding posts on the back.

I totally agree with your warnings concerning wall warts, from any one. I generally insert Anderson power poles between all my power sources, wall warts included) and add power poles to the plug wire that came with the device I am powering. Polarity is never a question and I can easily switch devices among supplies as needed..

So generally working from my main PS that also powers my rig is OK? If so then I will invest in a power pole distribution strip.. Thanks for the feedback.

6455. CAT cotrol of IC_718 with the AT-200ProII

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2013-09-02 22:40:57 UTC
From: Michael
Topic: 6455 Message: 6455

Guys, I have a nice new radio and tuner but I want to be able to do rig control via HRD. Unfortunately, the tuner uses the CAT jack on the IC-718, so if anyone know how to get around this, please let me know.

73 Mike, K7ELI

The Icom IC-718 uses Icom's CI-V format for remote control. If you look at the schematic for the CT-17 (page 31) you will see how "multiple connections" are made.
<http://www.difona.de/pdf_en/icct17_manual.pdf>

One of these should work nicely.
<http://www.ebay.com/itm/300768475667>

By the way, the rotary encoder on the front of the IC-718 is subject to catastrophic failure due to a large static discharge. If you kill yours, it's a $250 (or more) charge from Icom to repair it. I have a very simple method to prevent that from happening.

Hi Travis,

It's a switching supply and weighs almost 19 pounds according to information posted on the site below. .

I have done that search and very little comes up. Mostly about the 3030. No schematics, specs or anything. I have even searched for instruction booklets for the thing.
It works beautifully, I am just curious. Someday, I will pull the top off it and see it there is a good size transformer in it.

6469. Tuning Problem with YT-450

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2013-09-12 09:11:37 UTC
From: roley_g3vir
Topic: 6469 Message: 6469

I have a YT-450 which I am using with the Yaesu FT-950.
When I tune the antenna, regardless of band if the rig power was set to say 70 watts after tuning it resets to 50 watts. Also when setting up it's tuning procedure on any band, it keeps switching to 7MHz. After the tuning it always sets the 40 metre memory from the frequency I was on to 7026.72 and the mode switches to AM.
This does not happen with the internal ATU or another one which I borrowed to try.
My thoughts are that it must be a problem with the YT-450. Anyone out there any suggestions or also had this?

Thanks
Roley G3VIR

6470. Dead AT-100 Pro II

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2013-09-16 18:23:51 UTC
From: <n3tlq@...>
Topic: 6470 Message: 6470

Back at the end of June, I purchased an AT-100 Pro II to replace my old AT-11MP, and WOW, what an improvement! This morning I made some changes to one of my antennas, and I started doing some testing to see how the loading had changed. After about 5 or 6 seconds (cw keydown @ 60 watts) the lights on the tuner gave me a pattern that I'd never seen before, and they stayed on after unkeying the transmitter. (BTW, I'm using an old FT-747GX.) I shut down the power supply for 10 seconds, turned it back on and the 747 worked, but the Pro II was dead as a doornail. No lights, no clicks, no nuttin"! I checked the DC power-OK. The transmitter is only rated at 100 watts, so that shouldn't be the culprit, but on that antenna I sometimes have RFI issues. I opened the case and didn't see any obvious problems, but with all those surface mount parts, who knows??? Anyway, is there a way to reboot the unit, or something that I can do myself, or is it back to Maryland time?

TIA and 73 de Ron n3tlq

6471. Bypass

Yahoo group: LDG-auto-tuners (2010 — 2017)

From: <daniel.o39connell@...>
Topic: 6471 Message: 6471

A quick question: My AT 100 Pro II tuner immediately goes to Bypass when I go on 10 meters. Can I assume that is because my antenna is resonant, or close to it, on that band, and therefore makes tuning unnecessary?

Thanks, Dan O/KC2TRX.

Dan,

Bypass is one of the selections that the tuner checks when tuning. So if the tuner chooses bypass and the SWR is good, the tuner has done it's job.

Subject: [LDG-auto-tuners] Re: Bypass

Dan,

Bypass is one of the selections that the tuner checks when tuning. So if the tuner chooses bypass and the SWR is good, the tuner has done it's job.

Can anyone help me with doing a text search of the messages on our group? The only search feature I see is for searching by message number. If I had the message number, I probably wouldn't need to search.

Well it looks like Yahoo's effort to make it cute as removed any real
functionality. Go to the feedback page and it is almost totally
complaints. Add one that asks were the message search feature went.

Sure

Go to your groups page and at the top is a text box....

Enter your search term and click on Search Groups........

From: Pete Theer
Topic: 6476 Message: 6487

I'm a member of 57 Yahoo groups, Owner of 6 and moderator of two others. I can't delete any messages. I have my groups set up to send the group policy statement as a message to all members once a month and have been deleting them from the archive so group policy messages don't fill up the archive. The "neo" groups will no longer allow me to delete these (or any other) messages. It says "Deleting Message" but never does. Yes it looks that way but if you are in a group it finds messages... As I said I searched for the AT11 in this group and got a ton of hits. Have you actual;ly tried it? I have and it works for me...

It seems as if some of the "improvements" roll out to users at different times..

What is your antenna swr profile for the band in question it likely is not a flat line relationship.

Are you using a multiband antenna it likely does not exhibit the same profile shape on each band as they are a compromise.

Remember a tuner is making the antenna look like a perfect match to the transmitter in the radio.

Subject: [LDG-auto-tuners] Re: SWR Reading on Radio VS on LDG Tuner

I did some experimenting with my new AT1000 PRO II (also have a 100PRO II that is being replaced).

What I have noticed is that some times it does NOT actually find the best match. Some times its on the fringe and incorrectly selects the wrong Hi/LoZ. Under the circumstances that this happens I noticed that the SWRs are not matching the radio, by a significant amount...

I will do a comparison between the my AT PRO II 100 vs 1000 to give the rest of my findings in a different thread. With that said, there is surely something afoot. Can LDG chime in on this issue?

6497. RE: SWR Reading on Radio VS on LDG Tuner

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2013-10-09 13:24:34 UTC
From: <mikelebron@...>
Topic: 6419 Message: 6497

Unfortunately a good match to the rig does not always happen with the LDG tuners.. I have seen enough threads started with never answers from LDG (even LDG has emailed me back saying that there is nothing that can be done - pretty much live with it) as to why the tuners meter shows an acceptable SWR but the rig sees something as high as 1 or 1.5 SWR points higher. I can almost always after an auto tune when this occurs, tune the tuner using the manual controls to a significantly lower SWR which satisfies both the tuner and rigs SWR meter. Some times I can tune the match LOWER from the rigs meter than what the tuner sees! Its NOT the rigs meter as I have an external meter between the rig and the tuner and it confirms what the rig is seeing.

I do admit that this issue typically occurs where the SWR is above a 3:1 - but honestly my rigs tuner can tune up to a 4.5 :1.

The conclusion I have to come to is that the metering circuit on the LDG is not all that good and for now living with the need to manual tune the tuner sometimes (not always)... of course this defeats the purpose of an auto tuner. I may dump both units and either try another manufacturer or go to a manual tuner... Yes... I am upset about the service I have gotten for this issue.

---In ldg-auto-tuners@yahoogroups.com, <doug.pfaff@...> wrote:

What is your antenna swr profile for the band in question it likely is not a flat line relationship.

Are you using a multiband antenna it likely does not exhibit the same profile shape on each band as they are a compromise.

Remember a tuner is making the antenna look like a perfect match to the transmitter in the radio.

Same here - I use an AT-600 and the Z-100plus - excellent job (even when I use my 40 meter delta loop on the higher bands. They've been trouble free for me. (I have a manual Palstar AT2K and, using it, I can generally tweak for a lower SWR than I get with the automatic tuners but we are talking the difference, for example, between 1.2 and a perfect match ... so not significant).

Topic: 6419 Message: 6500

Mike,

I have the same issues with the tuner (AT-1000PROII and M-1000) as you. I use a lot of 450 ohm ladder line and quite frequently see different SWR readings between the PROIII and M-1000. When I ran a manual tuner the tuner readings and PROIII readings matched. Response from LDG has not been helpful. I'm not troubled by an SWR of, say, 1.5:1, but I would like to know why there's the continual difference. I guess I've been spoiled by my years in ham radio and have developed a need to know the "why" of things rather than just accepting the results when I push a button. Good luck, Mike.

Mike, W3QT

Hi Mike,

Based on my experience you likely have a stray RF
issue that can squared away with common mode
chokes on one or more cables to the ATU, D.C.
power, coax lines etc., an un-terminated port
(depending on the model in question) could
possibly be an issue but its not likely.

Once upon a time when I was younger and foolish I
brought open wire feed line into the station to
the back of the Roller Inductor tuner balun and
when I started using AATU that feed line was also
used on a well grounded balun located inside the
station as well, even though I learned how to
mitigate the effects, I ceased bringing any thing
but coax into the station, all balun's are
mounted outdoors in my operations. But even then
you have currents riding on the coax shield to deal with.

The other thing to address is all un-terminated
transmission lines if you have many antenna and
feed lines coming into the station, be sure to
run them all to ground either via unused port
grounding switch boxes or patch panel configuration.

Sincerely.

/s/ Steve, N2CKH

SWR will vary along a feedline if it is not a perfect 1:1.

In College, we did SWR tests along a feedline that was multiple wavelengths long. We measured the SWR at 1/4, 1/2, 3/4 and 1 wavelength. If the source impedance produces a 1.5:1 then you can measure different readings along the feedline.

Short story, don't worry about it. It is the physics of feedlines. Just keep the transmitter happy so it sees a correct match.

Everyone spends too much time on worrying about SWR because it is simple to measure. What you want to worry about what sort of signal you radiate and making sure you keep the RF off the feedline and in the feedline with chokes. :)

May I dispute your assertion?

I put the signal FROM my transmitter into the feedline, and expect my antenna to catch signals and feed them INTO my receiver. I believe that's the purpose of afeedline.

I definitely don't want signals to be kept off my feedline.

Note, I have zero, zilch,NADA, chokes on the open wirefeedlinewhich I use @ my station.

If you meant "keep unbalanced currentswhich will act as radiators and disrupt the pattern of the antenna from the feedline" then you're so right.

6505. RT-100 available in October of 2013

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2013-10-11 08:10:31 UTC
From: <ve5kc@...>
Topic: 6505 Message: 6505

LDG announced on their website that the RT-100 external tuner will be available in October of 2013. The LDG RT-100 is also showing on dealer websites for order or pre-ordering.

My current setup is working well for me with aprox 30 feet of coax between my internal tuner and the balun connected to the 300 ohm feed line connected to my antenna. I know that the mismatch is at the antenna and not at at the radio end of the coax but how much improvement can be expected by using this external tuner. How can we determine when changing from a tuner in the shack to the RT-100 external tuner will really make a noticeable improvement.

Any thoughts on this?

Any way, I will waiting to hear user reports on this new tuner, especially how well it handles cold winter temperatures

6506. RE: Re: [LDG-auto-tuners] RE: SWR Reading on Radio VS on LDG Tuner

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2013-10-11 14:18:43 UTC
From: <mikelebron@...>
Topic: 6419 Message: 6506

The fact of the matter is that the LDG Tuners have an issue with properly metering the SWR. I am not disputing the ability of the tuner but since it is labeled as an auto tuner my expectation is that the tuner tunes to the best possible match. Not he quickest match or the good enough match. Furthermore, that match should produce the same match that the rig sees with very little margin of error. I can see that there will be some margin of error due to cabling factors but not a full 1 to 2 SWR points difference.

And the notion (excuse) of some how the tuner being affected is hogwash. I have tested putting 5k Ohm impedance chokes on ever point of the run (right before the exciter, right before the tuner, right before entrance of my shack and at the antenna), I also have everything in my shack grounded now and I see NO difference. Very often when a relatively high swr is present, >2:1 match, the tuner can show a tune of a 1:1 while my rig sees a 2:1. If the tuner sees a 1.5:1 my rig can see a 2.5:1 so on and so on... All of which I can simply apply capacitance or inductance using the manual buttons on the tuner and achieve a lower, reasonable, equal match (rig = tuner swr). If I could not get the tuner to agree with the rig then I would then say that it is what it is... but it is not the case. I ALWAYS can get the tuner to equal the rigs SWR using the manual buttons. This phenomenon is worse with higher loss cabling - I use to run RG8x but now run RG8U to minimize the issue.

Between all that I have done to isolate any common mode, the fact that with manual adjustment the tuner and rig can be satisfied and others stating they have the exact same issue leads me to believe that the metering circuit and/or the tuning circuit on the tuner is faulty or a poor design.

And lastly, LDG has NEVER given me any comprehensible answer as to why this is occurring other than single sentence responses that say "Follow the Rigs SWR!!!" or "Nothing more you can do!", etc.

> The fact of the matter is that the LDG Tuners have an issue with properly metering the SWR.

You should be able to recalibrate your LDG tuner.

I think I might have posted this to this list before, but maybe it was a private response: On my Z-100 Plus and Z-11 there are a trimmer cap and two trimmer pots to calibrate the forward and reverse voltages from the sensor element. I wrote to LDG and asked how to calibrate my Z-1 and I got a reply that detailed the procedure.

Possibly they were more forthcoming with me because I mentioned that I had seen the adjustable elements on the schematic in my Z-11 manual. I have looked at the info on the LDG site and manuals for newer models don't seem to include schematics or "how it works" details. But it's likely the basic circuitry for sensing forward and reverse power is similar on newer models - there aren't too many ways to improve this, although certainly new models have more powerful microprocessors, more memory, and updated firmware programs.

If you can't find a schematic for your LDG unit look the QST archives on the ARRL site for the article by Dwayne Kincaid (January 1996) that describes the prototype for the AT-11, which LDG sold as a kit. The SWR sensor and relay circuitry are essentially the same as in the Z-11.

One caveat, it's possible the SWR sensor in your radio hascalibration adjustments, in which case the
difference might be the fault of the radio. However, it will be the SWR sensed by the radio, accurate or not, that will determine whether your output power is reduced.

From: <b.denley@...>
Topic: 6509 Message: 6509

This has happened before and is back again: every time I do a tune, the YT-450 changes my TX power from 100 to 50 and my AM carrier from 50 to 100. It's a pain to have to manually reset those menus (111, 112) every time I need to tune my antenna system. I made it stop once by doing a hard reset on the transceiver but now even that won't stop the problem. Anyone else ever experience this?

Date: 2013-10-21 18:52:45 UTC
From: <gntgrg@...>
Topic: 6511 Message: 6511

Dear Sir,
i want to buy a tuner for Yaesu 857.

I want to choose among Z-11 pro or AT-100 Pro 2.
The battery into the z-11 may be usefull but i read that at-100 is the perfect choice for 857 897 because if used also on v/uhf there are some problem with z-11 because some electrical output is also present on hf antenna.
I did not use v/Uhf.

I read also the led power indicator mey create some noise on at-100.

May you suggest wich is best to buy ?

Thanks Giorgio.

6513. RE: [LDG-auto-tuners] RE: SWR Reading on Radio VS on LDG Tuner

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2013-10-09 15:04:34 UTC
From: Doug - k4gkj
Topic: 6419 Message: 6513

I was getting no worse than 2:1 most of the time. Now I dont get anything better than 6:1 at all.
Something in the tuner has changed/gone bad.

This was a sudden issue...not one that happened to get worse over time.

I am certain that something has gone defective.
I am thinking that it may be the prom.

Anyone have ideas?

Subject: [LDG-auto-tuners] RE: SWR Reading on Radio VS on LDG Tuner

Unfortunately a good match to the rig does not always happen with the LDG tuners.. I have seen enough threads started with never answers from LDG (even LDG has emailed me back saying that there is nothing that can be done - pretty much live with it) as to why the tuners meter shows an acceptable SWR but the rig sees something as high as 1 or 1.5 SWR points higher. I can almost always after an auto tune when this occurs, tune the tuner using the manual controls to a significantly lower SWR which satisfies both the tuner and rigs SWR meter. Some times I can tune the match LOWER from the rigs meter than what the tuner sees! Its NOT the rigs meter as I have an external meter between the rig and the tuner and it confirms what the rig is seeing.

I do admit that this issue typically occurs where the SWR is above a 3:1 - but honestly my rigs tuner can tune up to a 4.5 :1.

The conclusion I have to come to is that the metering circuit on the LDG is not all that good and for now living with the need to manual tune the tuner sometimes (not always)... of course this defeats the purpose of an auto tuner. I may dump both units and either try another manufacturer or go to a manual tuner... Yes... I am upset about the service I have gotten for this issue.

Again, this tuner has been tested with several different rigs and even more different antennas, at different locations.
It is the tuner that is the problem.

And the issue started suddenly. The tuner was doing a fine job....

Subject: Re: [LDG-auto-tuners] RE: SWR Reading on Radio VS on LDG Tuner

Hi Mike,

Based on my experience you likely have a stray RF issue that can squared away with common mode chokes on one or more cables to the ATU, D.C. power, coax lines etc., an un-terminated port (depending on the model in question) could possibly be an issue but its not likely.

Once upon a time when I was younger and foolish I brought open wire feed line into the station to the back of the Roller Inductor tuner balun and when I started using AATU that feed line was also used on a well grounded balun located inside the station as well, even though I learned how to mitigate the effects, I ceased bringing any thing but coax into the station, all balun's are mounted outdoors in my operations. But even then you have currents riding on the coax shield to deal with.

The other thing to address is all un-terminated transmission lines if you have many antenna and feed lines coming into the station, be sure to run them all to ground either via unused port grounding switch boxes or patch panel configuration.

Sincerely.

/s/ Steve, N2CKH

6515. 600 pro II not tuning

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2013-10-20 04:44:34 UTC
From: laubachj@pacbell.net
Topic: 6515 Message: 6515

I have a 600 pro II connected to a ts 590s. I have double checked all wiring and it appears correct. My problem is with the power set to 10 watts output, my SWR is off the scale on 20 meters. My old mfj tuner worked fine and would tune this antenna . Is there a trouble shooting guide, I have tried tuning using CW and the phone. Any help would be appreciated

Thanks
John Laubach

6516. How do I recalibrate my Z-100Plus

Yahoo group: LDG-auto-tuners (2010 — 2017)

From: Steen Rudberg
Topic: 6516 Message: 6516

Hi

I have been reading the "SWR Reading on Radio VS on LDG Tuner" Conversation.

I have a Z-100 for portable use (WWFF) and a Z-100Plus for home use.
The Z-100Plus always gives a worse SWR after tuning than the Z-100.
As I see it when I open the boxes they have the same LC configuration - so they should bee able to tune to the same SWR under the same conditions. (That is the same antenna, cables, grounding ect)

Dose any of you have a calibration describtion?

It would bee nice with a "how to calibrate"folder here in the Yahoo group.

6518. Problems with Z817/FT817 only tuning on 2nd button push

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2013-10-04 18:03:30 UTC
From: <pa1wbu@...>
Topic: 6518 Message: 6518

hi all,

For the last month or 2 I have been struggling with my newly bought Z817/FT817 combo. The Z817 is essentially brandnew, the FT817 was bought new in July 2013.

What is wrong:

- pressing the tuning button for the first time does not make the FT817 go to PKT mode as it should. Obviously the tuning attempt fails with SSB, there is no HF for the Z817 to detect. While keeping the frequency constant an 2nd button push on the Z817 makes the Z817 go to PKT, and tune succesfully. Tuning keeps working on subsequent tuning button presses AS LONG AS you keep the frequency constant. If you change freq the 1st button press fails, the 2nd one works and tunes.

- Some X-checking proved that the issue stays with my new FT817. An older FT817 works with this tuner. Another Z817 which works with the older FT does not work with my FT.

- CAT on the FT817 works just fine, HRD is happy etc.

- I have been in contact with LDG support, they say they have not seen this before. They sent me a new CAT cable, which does not make a difference.

- I have seen some random reports on the WWW from people who appear to have exactly the same problem.

- To me this looks like a change by Yaesu in the FT firmware that makes communication behave differently with the Z817. LDG have confirmed they only ever delivered 1 version of Z817 firmware, aptly named V1.0

Are there other folks on this list who have the same problem? Maybe we can establish a pattern between serial# or age of the FT and the problem? Or maybe someone has a brilliant idea?

Yes, I agree with you completely.
The LDG 7000 tuner was working great on a G5rv (I see you shrugging!) And two other dipoles, one 40m, and one 80. For years it worked fine. But all the sudden it would act as if it was tuning, but it never found a good match.
I also hooked it up to another hf rig (same model - 706mk2g) and ended up with the same results.
Later that day I hooked it up to a friend's 7000 rig and his tribander beam, and the tuner still showed faulty results.

Long story short, it was working great for a long time till one day it wouldn't work well at all....for any rig that has been designed for it or any antenna that it has performed well with in the past.

6520. AT-100ProII, loop antenna?

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2013-09-30 21:45:20 UTC
From: MoonScryer K.
Topic: 6520 Message: 6520

Hello. Got a bit of a problem and hoping to get some help.
I live in a very restrictive apartment complex on the ground floor, studio apt. I have no balcony and no bushes to hide anything in so all my antenna wiring has to be indoors and hidden. I can't do a radial or counterpoise system as its too noticeable. Its a newer apartment complex so all the piping I can find is plastic. Yeah, so this is a worse case.

I am thinking of building a loop antenna around the ceiling perimeter. The room is 11x12ft. 9ft ceilings. There is a really odd deco moulding lip around the top the is low enough to hide a 6 or 8 guage wire in and I have a tall bookcase I can bring the wires down behind, so maybe 50-56ft counting the wire drop. Yes, I have been planning this.

I have an AT100ProII tuner w/ an FT857D. I don't think it can support a loop antenna without some sort of balun between the antenna ends and the coax. What should I get? If the AT100 can't do this, what tuner should I find? The 30watt max on digital is sort of an issue but need to solve this first.

Thanks.

6521. Issues with a LDG AT100proII and a AT-7000

Topic: 6521 Message: 6521

Hi all. I am having issues with a couple tuners and hope I may get some help without having to send the units in (will do what I need to do though).
First tuner is a LDG AT100pro2.
I took a surge it appears, or ????
I found the 5 volt voltage regulator to be bad, so I replaced it.
The new one I put in has a current limiter, so it won't blow so quickly when we have problems down the line, and in my case, I do. The new voltage regulater puts out a full 5 volts of power with the prom pulled, but with the prom in place, I only get .2 of a volt at both the volatage regulator output and pin one of the prom. a few components get warm too, mostly between the regulator and prom, but these test fine (caps, etc.) I am pretty confident the prom is bad, but LDG directed me to this group before I go to buying parts from them.... possibly due to thier experience in having similar issues with differnt culprits...???..
Willing to hear ideas from all that have a nodding knowledge here!!

The second tuner is a AT-7000. I have enjoyed this unit as a back up and for use during emergencies, field day, loaner, etc. This past field day it proved to be rather faulty though. it powers up and makes the noise it normally makes, but when all is done, it is not tuned properly....no mater what the band I have tested so far (20, 40, 60, and 80m). always used it with a 706mk2g, and tested it against another mk2g as well as a 7000 to make sure the radios and antennas werent to blame, and it is most certainly the tuner.... Ideas?

all ideas are welcome! I have a half way decent knowledge of electronics, but my eye sight and holding an iron steady is getting difficult...some days I am just fine... just age setting in...
and I have a decent amount of test equipment for my workbench... just need a little guidance on where to look (repairing a tv set or a juke box is easy, but specialty items that i don't crack open too often can throw me for a loop to be honest)

I thank everyone in advance for helping!

Topic: 6505 Message: 6522

What would really make sense is to ditch the 300ohm ladderline and mount the RT-100 exactly at the antenna feedpoint trough a 1:1 balun.

Use this to determine how much power are you losing because of standing waves on the feedline:

http://www.arrg.us/pages/Loss-Calc.htm http://www.arrg.us/pages/Loss-Calc.htm

---In ldg-auto-tuners@yahoogroups.com, <ve5kc@...> wrote:

LDG announced on their website that the RT-100 external tuner will be available in October of 2013. The LDG RT-100 is also showing on dealer websites for order or pre-ordering.

My current setup is working well for me with aprox 30 feet of coax between my internal tuner and the balun connected to the 300 ohm feed line connected to my antenna. I know that the mismatch is at the antenna and not at at the radio end of the coax but how much improvement can be expected by using this external tuner. How can we determine when changing from a tuner in the shack to the RT-100 external tuner will really make a noticeable improvement.

Any thoughts on this?

Any way, I will waiting to hear user reports on this new tuner, especially how well it handles cold winter temperatures

I have one of the very first AT1000 tuners from LDG bought new and never had a problem for 6 years until I used it for 6m recently. In a nutshell, the thing smoked and upon opening it, I found a burned relay. Phone calls and emails to LDG have gone unanswered. Amazon shows a relay with the same number, but, it has a clear plastic see-through housing unlike the black housing in the LDG one. Would this work? Or better yet, where the hell can I find an original replacement?

6524. Z-11 Pro II - not finding best match?

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2013-10-08 01:54:01 UTC
From: <n2htt.mike@...>
Topic: 6524 Message: 6524

Hello everyone, I am new to the group and wanted to throw a question out to see if anyone else has experienced this. I have a Z-11 Pro II which I have used for several years now with my home station. I run it from batteries, and since I mostly operate QRP I am typically tuning up with about 1 - 3 watts.
I have noticed recently that when I do a full manual tuning cycle, it stops at around 2.5 - 3.0:1, and I can always add a little inductance manually to bring the solution down below 2:1. It always takes a little additional inductance to get a good match.
My antenna is an 88 foot doublet fed with window line, with a 4:1 balun and a short run of coax attaching the tuner to the antenna.
Has anyone ever seen this before, or would anyone have any suggestions on how to improve the match?
Thanks and 73
Mike N2HTT

6525. RE: Re: YT-450 problem on FT-950

I had the same problem, it seem to start when I an issue getting tuned. Nothing I did to the FT950 helped, I just got use to changing the AM carrier to lower power before I would Tune. Then one day I had an issue tuning and it was cleared up and everything worked correctly again. I'm pretty sure it was in the FY450, not the 950. Sorry I can't say what fixed it, I'm just hoping it doesn't come back.

I have the same problem and I have seen posts here from others that also have this problem. Not long ago it suddenly stopped doing this but it is back again.
Any comments from Wayne at LDG? I know he monitors this group.

>
> This has happened before and is back again: every time I do a tune, the YT-450 changes my TX power from 100 to 50 and my AM carrier from 50 to 100. It's a pain to have to manually reset those menus (111, 112) every time I need to tune my antenna system. I made it stop once by doing a hard reset on the transceiver but now even that won't stop the problem. Anyone else ever experience this?

Topic: 6526 Message: 6526

I have a Z-11Proll between my ft-857d and my s943 vertical...worked great until a recent spike of some un identified source(likely me)....

Is there ANY schematic for this unit so I can pin it down, I don't know what an "average" repair bill is via LDG, but any more than 50.00 will be reason to go back to a beefier MFJ remote tuner and salvage serviceable components from the ldg.

Any help would be much appreciated!!

Use a 9:1 balun to match the 450 ohm window line. It will be much happier.

Correct me if I am wrong, but this is only true if the signal at the end of the ladder line happens to match 450 Ohms. To get this to be true would be a remarkable coincidence. For one thing, to match the 450 Ohms, most antennas will need some transformation at the connection of the feed line to the antenna. (The other end of the feed line)
The attraction of ladder line is not easy matching, it is low loss when NOT matched, which is in most cases. There is a figure showing this loss for many types of transmission line in the ARRL Handbook.
To match Ladder line to 50 Ohm coax, one must determine0 (some way) the characteristics of the signal at the juncture, not what the label says.

Mike,

Here's my suggestion. Remove the 4:1 balun and replace it with a 1:1 choke balun (plenty of articles on the net on how to build an "ugly" balun). Instead of trying to match with the balun (because one size may not fit all) let the tuner do the work for you. With the antenna you have you will be looking at a wide range of impedances depending on frequency, so the 4:1 may be more of a hindrance than a help. In other words, as W4BSG suggests but in slightly different language, you just can't take 450 divided by 50 and get a 9:1 balun as your ticket to a match because your impedance may not be 450 ohms. Also, make sure you keep the coax from the balun to tuner as short as you can. Those losses can be a problem depending on coax length, type, etc. and, with running 1-3 watts, you certainly don't need that. Just a suggestion, but I suspect worth a try.

6530. Re: [LDG-auto-tuners] AT-100ProII, loop antenna?

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2013-10-31 03:54:03 UTC
From: Kirk Kleinschmidt
Topic: 6520 Message: 6530

MoonScryer,

I have successfully used loops of this type in the past with manual and autotuners.

Coupla thoughts:

1. The 30-W limit isn't really an issue, as FCC/common sense RF exposure guidelines would likely be exceeded at or beyond 30 W for an indoor antenna regardless of mode. Any more than that and you're gonna couple RF into your ac wiring...with potentially bad results for delicate ac-powered devices... You'll also likely trip GFCI outlets and breakers...

2. I strongly suggest placing the tuner at the antenna feed point and placing the 1:1 coaxial balun on the input of the tuner. This will eliminate SWR losses in any coax that might run between the tuner and the antenna. With small antennas these losses can be extreme.

3. If you can't do that, use beefy 300-ohm twinlead (okay) or 450-ohm ladder line (better) or true open-wire line for the run between the tuner and the feed point (best). This will essentially eliminate any feed line SWR losses. Using coax between the tuner and the feed point with these physically small antennas can be cripping. 20+ dB losses are common.

I just proved that point in my own shack. I have a 40-meter horizontal loop that runs around the perimeter of my attic. My autocouplers (a Z11 Pro II and an SGC SG-231) live just inside the attic access hatch, which is mostly centrally located. This setup has been a star performer for years at 5-10 W, even producing DXCC (and soon 5BWAS) WAC on 80 meters and several DXCC entities on 160.

Because the SGC is slightly "goofy," and needing service, I switched to the Z11 two years ago. A 70-foot run of RG-6 connects my shack to the attic tuner, and a 25-foot (approx) run of open-wire line connects the Z11 to the feed point (no balun). Well, the balun (coax loops) is actually on the coax, right at the tuner input.

As mentioned, this works really well, and there are days I hardly notice that I'm using a compromise antenna. The Z11 doesn't like MN winter temps, however, so when it's 10 above (or colder), the tuner just won't tune. As a short-term remedy, I moved the tuner to a second-floor bedroom and ran 20-25 feet of coax from the tuner to the open-wire line (coaxial balun at the transition).

It TUNES sweet, but it's practically a dummy load compared to the previous setup. Before last weekend's CQWW SSB contest I put the tuner back in the attic, and POW! The good old days are here again! But winter is also coming...so I'll have to rig a styrofoam box with a low-wattage heat tape (or something) to keep the Z11 warm...or I'll have to fix the SG-231, which isn't affected by cold temps.

At any rate, I HIGHLY RECOMMEND placing the tuner at the feed point or using ladder line between the tuner and the feed point.

Good luck,

6531. KT-100 mobile photo album

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2013-10-31 06:46:17 UTC
From: Avery
Topic: 6531 Message: 6531

I have created a photo album and uploaded photos of my new mobile installation of a TS-480 with a KT-100 tuner and an SG-303 antenna. I am not finished with this installation and would appreciate advice for improvements. This vehicle does produce a lot of noise so I know I am not finished with noise reduction work. I have added a few ground bonds, which did help, so I am planning on adding more ground bonding as I get time. The electric fuel pump was very noisy (This Ford model is notorious for that), but I have added filtering in the power lead which has helped a lot. So far, this seems to work well on 40 meters (lowest noise) and 20 meters (significant noise, but also strong signals when open). On 80 meters, the KT-100 won't tune the SG-303 below about 10:1, but tunes higher bands fine. What can I do to help the KT-100 tune the SG-303 on 80 meters? I tried a much shorter coax, and that didn't help.

I actually think that a closer look at this antenna would show that the 300 ohm ladder line is a necessary part. M space is very limited, nothing I can control and more over this antenna works very good.

If I was to try a RT-100 it would be placed between the coax and the 300 ohm ladder line, eliminating the balun. The big question, what would really be be gained by this.

73.. Ken - VE5KC

---In LDG-auto-tuners@yahoogroups.com, <ldg-auto-tuners@yahoogroups.com> wrote:

What would really make sense is to ditch the 300ohm ladderline and mount the RT-100 exactly at the antenna feedpoint trough a 1:1 balun.

Use this to determine how much power are you losing because of standing waves on the feedline:

http://www.arrg.us/pages/Loss-Calc.htm http://www.arrg.us/pages/Loss-Calc.htm

---In ldg-auto-tuners@yahoogroups.com, <ve5kc@...> wrote:

LDG announced on their website that the RT-100 external tuner will be available in October of 2013. The LDG RT-100 is also showing on dealer websites for order or pre-ordering.

My current setup is working well for me with aprox 30 feet of coax between my internal tuner and the balun connected to the 300 ohm feed line connected to my antenna. I know that the mismatch is at the antenna and not at at the radio end of the coax but how much improvement can be expected by using this external tuner. How can we determine when changing from a tuner in the shack to the RT-100 external tuner will really make a noticeable improvement.

Any thoughts on this?

Any way, I will waiting to hear user reports on this new tuner, especially how well it handles cold winter temperatures

I wouldn't worry about keeping your tuner warm. The box should be enough.

On my remote base, my TS480, Steppir IR controller and rotator controller routinely see -25C and they have never had an issue. I don't use any heaters at all.

Topic: 6505 Message: 6534

There are very few antenna that REQUIRE ladderline to become resonant. And if your using an external coupler than I assume your antenna is not resonant. So, if that is the case I would ditch the ladder line and transformer and directly connect the coupler to the antenna with as short leads as you can running high quality coax from the OP to the coupler.

The only reason some antennas require ladderline is for impedance transformation. The 450 or 300 Ohm ladder line changes the impedance to bring it closer to 50 Ohms.

If your antenna is a simple doublet or other derivative of a dipole that is already close to 50 Ohms on 1 or more bands than ladderline is NOT needed except where your concern is losses due to high SWR over the coax. There are many good reason to have a very long run of ladderline to coax... when there are high SWRs present over the feedline.

Furthermore, ladderline ALWAYS radiates - that could be a bad thing OR a good thing... it all depends. No matter what the pattern is always skewed using ladderline. When using a resonant antenna there is little effect, when using an anetnna system that relies on ladderline the pattern is distinct to that antennas nature like a G5RV. If your looking for a pure dipole pattern / characteristic then the couple at the feed point of the antenna will yield this.

Lastly the balun that transforms the impedance from the ladderline to the coax is lossy, that is added loss to your antenna system. Of course the amount of loss depends on the quality of the balun.

Your total losses will depend on how high your SWRs are now. If your highest SWR is lower than 3:1 and your coax is of high quality like RG213, LMR400, etc. with 30 feet there is not enough loss to make a difference. If your running RG8x, RG58, low quality RG8 then your losses could be higher than you would like. If your SWR is >3:1 or a 5 10 20 :1 (without the OP tuner) then you will see a significant improvement.

Ideally you want to remove as many connectors, transformers, etc. from the antenna system to be most efficient. The best antenna system is one that provide a conjugate match. You need a losses feedline system and a 50Ohm antenna to achieve this. The coupler gets you closest to this if you do not take into account the losses the coupler introduces and the losses the coax introduces due to distance and nature of any feed-line system..

Lastly, if you want to save expense, run the ladderline directly into or near the shack and hook it up to like a 10 foot piece of high quality coax if your tuner cant directly take ladderline... you will accomplish the same thing as buying the coupler and save a fair amount of $$.

What makes non-resonant antennas work and tuning simple is a continuous piece of transmission line of a given impedance between the antenna and the tuner without any introduced mismatches.

Introducing a "bump" such as using a 4:1 balun between 50 ohm and 450 ohm transmission line is adding to the problem.

Additionally using a 9:1 balun changes the "solution range" of the tuner, and provides an easier match.

Correct me if I am wrong, but this is only true if the signal at the end of the ladder line happens to match 450 Ohms. To get this to be true would be a remarkable coincidence. For one thing, to match the 450 Ohms, most antennas will need some transformation at the connection of the feed line to the antenna. (The other end of the feed line)
The attraction of ladder line is not easy matching, it is low loss when NOT matched, which is in most cases. There is a figure showing this loss for many types of transmission line in the ARRL Handbook.
To match Ladder line to 50 Ohm coax, one must determine0 (some way) the characteristics of the signal at the juncture, not what the label says.

Use a 9:1 balun to match the 450 ohm window line. It will be much happier.

Hello everyone, I am new to the group and wanted to throw a question out to see if anyone else has experienced this. I have a Z-11 Pro II which I have used for several years now with my home station. I run it from batteries, and since I mostly operate QRP I am typically tuning up with about 1 - 3 watts.
I have noticed recently that when I do a full manual tuning cycle, it stops

at around 2.5 - 3.0:1, and I can always add a little inductance manually to bring the solution down below 2:1. It always takes a little additional inductance to get a good match.
My antenna is an 88 foot doublet fed with window line, with a 4:1 balun and a short run of coax attaching the tuner to the antenna.
Has anyone ever seen this before, or would anyone have any suggestions on how to improve the match?

Jeff:

The purpose of a balun for impedance translation is to NOT cause a "bump" at the junction of two dissimilar lines.

You are of course correct that using a balun for impedance transformation might help a tuner achieve a match to a load that is out of its normal range. That would be true for any ratio other than 1:1 as long as it transforms the load impedance into the range of the tuner.

Chuck,

Let me second your statement: "as long as it transforms the load impedance into the range of the tuner." That, in my opinion is a prime reason NOT to use the 9:1. The feedpoint impedance of a doublet fed with ladderline can vary widely from well under 50 ohms to several thousand. You would have a better chance of hitting the Powerball than hitting a 50 ohm impedance with a 9:1 balun, but the downside may be considerable - even if it does tickle the tuner. Suppose the SWR is 10:1 at a certain operating frequency (many times actually much higher). The feedpoint impedance would be 450/10 = 45 ohms. A 9:1 balun would take that down to 5 ohms. Tuners work better at high impedances (lower loss in the transformation). When faced with 5 ohms, tuner losses would be high. I think one has to question whether getting a match by using the 9:1 balun would be worth the high loss. You can guess my opinion. I'd go with a 1:1 balun (current), play with the feedline length and try to move into the tuner's range. If, as Mike initially stated, he runs QRP, 1-3 watts, significant tuner losses, not to mention other losses in the system, depending on the frequency, would quickly take him from 1-3 to less than half that.

Jeff-
So, a 4:1 “Bump” is bad, but a 9:1 “Bump” is good? How does 1:1 do?
Bill—W4BSG

Subject: Re: [LDG-auto-tuners] Z-11 Pro II - not finding best match?

What makes non-resonant antennas work and tuning simple is a continuous piece of transmission line of a given impedance between the antenna and the tuner without any introduced mismatches.

Introducing a "bump" such as using a 4:1 balun between 50 ohm and 450 ohm transmission line is adding to the problem.

Additionally using a 9:1 balun changes the "solution range" of the tuner, and provides an easier match.

I have exactly the antenna combination that you have (88 foot doublet, 4:1 balun), and my Z-11 Pro ll
tunes just fine from 80 - 6 meters. I wonder how long your twinlead is? Mine is 32 feet down to the balun which is outside with about 12 feet of high quality LM coax into the shack. Length of the twinlead is another "handle" for matching non-resonate antennas. I have had success with 32 feet for both 88 and 102 foot antennas. My Elecraft BL-1 balun is switchable for either 4:1 or 1:1 ratio and I have been using 4:1. Both ratios work. I need to experimentally determine which ratio is optimal for my combination. I agree that 9:1 is probably not desirable. For freqs where impedance at the balun is already low, a 9:1 ratio may make it untunable. This is the best wire antenna I have ever used and I highly recommend it. Fits on most residential lots too!

I hope a box will be sufficient, but I still have a few doubts :) In my attic, which isn't exposed to anything more than a slight breeze / minimal air movement, the Z11 Pro II "stops" working at about 10 F. The stand-by current is very minimal (as my cheap batteries demonstrate), but it might be enough to keep things working if the tuner is sealed in a styrofoam box. Attic temps here range from -25F to +120F. (My older SGC tuner has never been temperature sensitive, but it's brain-damaged right now, so it needs attention. Plus, it seems to need a bit more RF to initiate a "tune," which has been frustrating at times when using 1-3 W radios.)

In case a box isn't sufficient, I'm open to suggestion about a teeny-weeny heat source that won't burn down my house like a rogue, unattended light bulb might, etc, as the tuner is in the attic and is only visible if I open the ceiling hatch from the top of a ladder :)

Something like a 2-watt Peltier module, etc?

As always, thanks for your input!

Try a 5-10W 12V incandescent bulb for a heat source. As long as you are in a insulated box it should be adequate. You could use something like a MFJ4116 on each end to send the DC up the cable to provide the power for the bulb and the tuner so you wouldn't need to run a separate power line..

Kirk - maybe just a closet shelf adjacent the attic with a very short run of whatever open wire feed into the attic?

I had a similar issue with my 200 pro thinking I might need it just outside the house but ended up with it inside in a closet and a careful short run of window line through the wall and could see no difference that way, and been really happy with that for almost five flawless years, and getting ready for same deal with a kW model here at the new QTH.

Good luck.

Sigh.... 450 / 9 = 50
A 9:1 balun makes the 50 ohm coax look like a contiguous section of feed line when used with 450 ohm ladder line.

450 / 4 = 112.5
This places a discontinuity in the feed line. I.e. a "bump"

Subject: Re: [LDG-auto-tuners] Z-11 Pro II - not finding best match?

What makes non-resonant antennas work and tuning simple is a continuous piece of transmission line of a given impedance between the antenna and the tuner without any introduced mismatches.

Introducing
a "bump" such as using a 4:1 balun between 50 ohm and 450 ohm transmission line is adding to the problem.

Additionally
using a 9:1 balun changes the "solution range" of the tuner, and provides an easier match.

Bill Aycock <billaycock@...> wrote:

Correct me if I am wrong, but this is only true if the signal at the end of the ladder line happens to match 450 Ohms. To get this to be true would be a remarkable coincidence. For one thing, to match the 450 Ohms, most antennas will need some transformation at the connection of the feed line to the antenna. (The other end of the feed line)
The attraction of ladder line is not easy matching, it is low loss when NOT matched, which is in most cases. There is a figure showing this loss for many types of transmission line in the ARRL Handbook.

To match Ladder line to 50 Ohm coax, one must determine0 (some way) the characteristics of the signal at the juncture, not what the label says.

Use a 9:1 balun to match the 450 ohm window line. It will be much happier.

Hello everyone, I am new to the group and wanted to throw a question out to see if anyone else has experienced this. I have a Z-11 Pro II which I have used for several years now with my home station. I run it from batteries, and since I mostly operate QRP I am typically tuning up with about 1 - 3 watts.
I have noticed recently that when I do a full manual tuning cycle, it stops at around 2.5 - 3.0:1, and I can always add a little inductance manually to bring the solution down below 2:1. It always takes a little additional inductance to get a good match.
My antenna is an 88 foot doublet fed with window line, with a 4:1 balun and a short run of coax attaching the tuner to the antenna.
Has anyone ever seen this before, or would anyone have any suggestions on how to improve the match?
Thanks and 73

6544. Tuner wish list

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2013-11-01 14:05:14 UTC
From: Joe
Topic: 6524 Message: 6544

While reading an article in QST regarding the use of a G5RV on 160 meters I thought about my old MFJ tuner that I had years ago. It had antenna outputs for balanced, unbalanced and long wire antennas. Although it was far from the most efficient tuner, it did get me on the air from several locations that I could not erect a full size antenna. I used it in Sint Maartin during a vacation to load up to a long wire antenna thrown out in the trees. Thinking back, the antenna was probably half in the French side and the the in the Dutch side. I was using a Dutch VP7 call and the transmitter was on the Dutch side, so it was probably legal. I digress, but that is allowed with age......

I would like to see an LDG box that could do the same thing, able to reasonably match to a G5RV, dipole, wire, etc. It would be nice to have both a 1:1 and 4:1 baluns included in the package. I know that there would be a compromise in size, but the ability to have everything in one package (and not lose or forget something) would be nice for a GoBox or QRP setup. Maybe the baluns could be an option to install? Again, I realize that this would be a compromise but sometimes the local environment dictates what size antenna you can erect and getting on the air is more important than efficiency.

Any thoughts?

Jeff, isn't the real issue feedpoint impedance? You say the 9:1 makes the feedline look like a contiguous 50 ohm line. For it to be a contiguous 50 ohm feedline from one end to the other wouldn't you need a 9:1 balun on each end of the 450? That aside, the issue really isn't matching 450 ohm line to a piece of coax, is it? If it were, why not just use a run of coax? A 9:1 balun makes sense only if you know the feedpoint impedance and the mismatch isn't such that you flummox the tuner. Impedances of a wire antenna used over a wide range of frequencies vary widely (a few tens to several thousands of ohms), which is why one uses ladder line, anticipating the need for a low loss feedline. Seldom does a 9:1 balun look at 450 ohms, so you can divide 450/9 and get 50, but you haven't taken care of the mismatch. For example, if the SWR were 10:1 (very reasonable number for a multiband wire antenna fed with ladder line) the feedpoint impedance would be 450/10 or 40 ohms. A 9:1 balun would transform that to roughly 4.5 ohms, and losses would be prohibitive. The real concern when using a tuner is efficiency, and that can be all over the ballpark depending on antenna design. Better to use a 1:1 current balun, transform from balanced to unbalanced and then let the tuner do its job. If it can't then adjust the length of the feedline until it can. If the 9:1 works for you, have fun, but there may be a more efficient way.

Thanks, Leonard, good idea!

I was worried about using a 120-V bulb, but a low-wattage dc lamp would probably work just fine without being a fire hazard. Plus, the light would probably help me see what I'm doing on those occasions where I need to fuss with the remotely-installed tuner...

The RG-6 feeding the attic tuner has an external, insulated "pilot wire" that I use for sending 12-V dc to the tuner (RF on the center conductor and the coax shield, dc on the pilot wire and the coax shield). Works well and doesn't require a bias tee, etc. Voltage drop, even on 100-foot runs (measured on previous installs) wasn't significant, even though the wire is steel.

Thanks again,

To minimize the probability of fire to approaching the infinitesimal
(one can NEVER eliminate the probability of fire or explosion, or
implosion, for that matter), you might install a thermostat fixed at
some low temperature, like 50 degrees Fahrenheit or 10 degrees Celsius
in series with the light bulb. If you use a 12 volt bulb, the
thermostat would work directly with no need for a relay.

Hank,

Good idea!

You're talking about an old-school, bi-metallic thermostat like the ones we used to use with our furnaces, right?

Just set a temp and connect it in series with the 12-V dc?

--Kirk, NT0Z

My book, "Stealth Amateur Radio," is now available from www.stealthamateur.com and on the Amazon Kindle (soon)

I agree with Mike's comments. Often we attempt to press into service a transmission line of random length and fixed impedance with the hope that an antenna tuning unit will correct for whatever RF reactances and voltage appears at the transmitter. To maximize the performance of the antenna, transmission line and tuner as a complete system, we should optimize the performance of each component.

I use a 40 meter full wave horizontal loop and an LDG Z-11Pro II tuner with an attached 1:1 current balun on all bands from 80 through 10 meters including the WARC bands. The antenna feed point presents an impedance that varies between 80 to 1800 ohms over that range, and the LDG Z-11Pro II had difficulty matching the transmitter to a random 37 foot feed line that I originally used. By studying the impedance transforming characteristics of feed lines, I found a sweet spot for operating on all these frequencies with a 100 ohm feed line lengthened to 51 feet (1/2 electrical wavelength on 7 MHz).

My write up is at
http://www.qsl.net/kp4md/kp4mdnec2.htm#80m http://www.qsl.net/kp4md/kp4mdnec2.htm#80m

Carol, KP4MD

Update - 28 August 2013 - 40 Meter Loop Antenna Transmission Line Optimization for 80 Meters and WARC Bands As seen above in Figures 35 and 36, the 40 meter full wave loop antenna presents a non-reactive load on its resonant frequency and harmonics thereof, but its high impedance between these frequencies presents matching problems at the transmitter end of the transmission line. In addition, the impedance transforming properties of random transmission line lengths skew the resonant frequencies seen at the transmitter end of the feed line.
The vector network analyzer measurements at Figures 51 and 52 below demonstrate this effect measured at the transmitter end of the original random length 37.9 foot zip cord transmission line. Not only were the resonant frequencies skewed outside of the desired frequency bands, but the high impedance presented to the transmitter on the 80 meter and the 30, 17 and 12 meter "WARC" bands rendered impedance matching problematic at those frequencies.
Figures 53 and 54 demonstrate the effect of lengthening the zip cord transmission line to an electrical half-wavelength at 7 MHz (51 feet). This eliminated skewing of the natural resonant frequencies of the loop antenna at its natural fundamental and harmonic frequencies. Also, the impedance transforming characteristics of this transmission line at frequencies where it is also an odd multiple of a quarter-wavelength (3.5, 10.5, 17.5, and 24.5 MHz) transformed the loop antenna's high impedance at those frequencies to a low impedance, eliminating high RF voltage on the matching network and facilitating transmitter matching on 3.5 MHz and the WARC bands.
The principle of the 7 MHz full-wave loop operation on 3.5 MHz may be conceptualized by comparison with the HO loop, or halo antenna—a half-wave open loop antenna popular on VHF frequencies. The halo antenna is essentially a horizontal half-wave dipole with its elements curved to form an open-ended circular loop to provide a nearly omnidirectional radiation pattern. The halo antenna is typically fed at its low impedance center point, while its open ends exhibit high impedance. By analogy, the 7 MHz full-wave loop operates

on 3.5 MHz as a half-wave halo antenna fed across its high impedance open ends. In this case, the impedance transforming characteristic of a 1/4 wavelength transmission line assists in coupling the high impedance antenna to the low 50 ohm impedance of the transmitter. This situation repeats at frequencies where the loop antenna is an odd multiple of a half-wavelength, that is, at 10.5, 17.5 and 24.5 MHz, near the "WARC" frequency bands.

The 100 ohm zip cord is preferable to 300 ohm twin-lead and 450 ohm ladder line for this application. As can be seen in Figure 37, the loop impedance varies between 80 and 350 ohms at its resonance points and between 800 and 1800 ohms at the midpoint peaks between resonance. For a quarter wavelength transmission line, the impedance seen by the transmitter (Z) is given by Z = Z02 / Zant, where Z0is the characteristic impedance of the transmission line and Zant is the antenna impedance. Figures 55 and 56 compare these impedance transforming characteristics for 100 ohm and 450 ohm feed lines. The 100 ohm feed line transforms the impedance to 6 to 125 ohms at the transmitter, within the range of most antenna tuning units. However, a 450 ohm feed line renders an impedance range of 110 to 2500 ohms at the transmitter, values that exceed the operating range and safe voltage ratings of most antenna tuners.
Horizontal Loop Antenna Parameters Measured at Transmitter End of Feed Line over 3 to 30 MHz

From: Hank Greeb
Topic: 6524 Message: 6550

In the 61 years of hamming, I've rarely found it difficult to empirically determine a "sweet spot" of antenna feedline as long as the dipole is ~3/8 wavelength or greater on the highest wavelength that one is expecting to use it. I've found (and subsequently confirmed by Cebik, W4RNL) that a 1/4 wave dipole is very finicky for matching, so I try to use a longer length. I generally use ~400 ohm ladder line or window line as feeder, just because of habit. Sometimes the the length from the middle of the antenna to the shack is < the optimum length, so the feeder dribbles around the back yard. Prior to the ready availability of 400 ohm line I made my own ladder line with wooden dowels soaked in paraffin as spreaders.

Typically the "sweet spot" is not all that critical with any reasonably wide range matching unit. With some of the comercially made units the range for matching is not sufficient, so I either resort to my trusty homebrew tuner, which I made in the 1960's or I experiment more until I find a better "sweet spot" of length.

He who is not an experimenter within ham radio is doomed to occasional failure. (Maxim by Hank Greeb, N8XX, ex WNØFVD, ex WØFVD, ex W8CHT

p.s. If you can get hold of the ARRL Antenna Book 1941 version, it will be very useful in understanding transmission line theory. Until I misplaced it shortly after moving to Michigan in 2005 it was in regular use. Later versions of this Book seem to have less practical stuff and more high-falutin' theory which is several stories above my level of interest and therefore waaaayyyy above my comprehension.

I use a Freeze Alarm device that I purchased at the local hardware store. You plug it in the wall, then plug a lamp into it. When the temp goes below a preset point the light turns on. This is meant to alert your neighbor that your heat is off when you are on vacation. I use one of these in my 6 meter repeater cabinet to keep things warm during the winter.

Or, you can use a electric baseboard thermostat. They are made to switch 110 or 220 VAC directly.

Just be aware that by heating a box in the attic during the winter is going to invite guests. Protect against mice getting into or on the top of the box.

Jeff--
I appreciate the arithmetic lesson; I learned that before you were born. Hell, I was licensed before you were born. However, even you should know that the characteristic impedance of a transmission line only represents the character of the signal on a PROPERLY TERMINATED line. Sticking a transformer on one end of a line does not do it; both ends must be considered, or reflections occur. Proper selection of a transmission line transformer requires knowledge of the signal that isn't known in the situation we are talking about.

Subject: Re: [LDG-auto-tuners] Z-11 Pro II - not finding best match?

Sigh.... 450 / 9 = 50
A 9:1 balun makes the 50 ohm coax look like a contiguous section of feed line when used with 450 ohm ladder line.

450 / 4 = 112.5
This places a discontinuity in the feed line. I.e. a "bump"

Subject: Re: [LDG-auto-tuners] Z-11 Pro II - not finding best match?

What makes non-resonant antennas work and tuning simple is a continuous piece of transmission line of a given impedance between the antenna and the tuner without any introduced mismatches.

Introducing a "bump" such as using a 4:1 balun between 50 ohm and 450 ohm transmission line is adding to the problem.

Additionally using a 9:1 balun changes the "solution range" of the tuner, and provides an easier match.

Jeff-1.0
wa6fwi

On Wednesday, October 30, 2013 5:54 PM, Bill Aycock <billaycock@...> wrote:

Correct me if I am wrong, but this is only true if the signal at the end of the ladder line happens to match 450 Ohms. To get this to be true would be a remarkable coincidence. For one thing, to match the 450 Ohms, most antennas will need some transformation at the connection of the feed line to the antenna. (The other end of the feed line)
The attraction of ladder line is not easy matching, it is low loss when NOT matched, which is in most cases. There is a figure showing this loss for many types of transmission line in the ARRL Handbook.
To match Ladder line to 50 Ohm coax, one must determine0 (some way) the characteristics of the signal at the juncture, not what the label says.

Hello everyone, I am new to the group and wanted to throw a question out to see if anyone else has experienced this. I have a Z-11 Pro II which I have used for several years now with my home station. I run it from batteries, and since I mostly operate QRP I am typically tuning up with about 1 - 3 watts.
I have noticed recently that when I do a full manual tuning cycle, it stops at around 2.5 - 3.0:1, and I can always add a little inductance manually to bring the solution down below 2:1. It always takes a little additional inductance to get a good match.
My antenna is an 88 foot doublet fed with window line, with a 4:1 balun and a short run of coax attaching the tuner to the antenna.
Has anyone ever seen this before, or would anyone have any suggestions on how to improve the match?
Thanks and 73

Shucky durn. If I have a 400 ohm line and feed it from a 50 ohm source, and it has SWR=10, the LDG Z-11 may or may not be able to handle it. But, there ain't no "discontinuity" or "bump."" If the current or voltage limits for the Balun are NOT exceeded, the balun acts and a transformer and reduces both the reactive and resistive components by a factor of 4. Nothing more, nothing less.

If the input impedance is outside the range of the Z-11 matching device, maybe you will do better with a 9/1 balun, or maybe you'll do better with a 1/1 balun. I find very few lengths of center fed antennae (when the center fed antenna is => 3/8 wavelength at the operating wavelength) plus length of 400 ohm window line (polyethylene insulated, with varying sizes and spacing of "windows") which are unsuitable if I use either a 4/1 or 1/1 balun. I always have 1 each of these in my "bag of trix. I don't use a Z-11, but one of the original Z-100 units.

A bit of experimentation of the length of balanced feeders (either 300, 400, or 600 ohm nominal impedance) and use of either 4/1 or 1/1 Balun will result in satisfactory match >99.44% of the time. At least that's been my experience over the past 4 years during which I've owned the ancient Z-100 tuner.

I find the discussion a bit like the blind leading the blind. I suggest that folks get hold of most any version of the ARRL Antenna book or similar tome, read it, and then do some experimentation. The experimentation should be very useful.

Expecting miracles to overcome the laws of physics is fruitless - it ain't gonna happen.

72/73 de n8xx Hg
QRP >99.44% of the time

p.s. one CAN burn up a LDG 4/1 voltage balun if the wrong choice of feedline and antenna length is made. We proved that during Field Day a couple years ago, but it was our own fault - we didn't take the time to figure out the impedance which was presented by a much shorter than usual feedline length with an antenna which I usually use at home.

Are you using batteries to power it ? like a AA pack or such?

If so,might be them being to cold.. I'd power the tuner through a set of bias-t's.. That's how I power my Z11Pro at the base of a 31'vert.

Scott W0SGM

---In LDG-auto-tuners@yahoogroups.com, <ldg-auto-tuners@yahoogroups.com> wrote:

I hope a box will be sufficient, but I still have a few doubts :) In my attic, which isn't exposed to anything more than a slight breeze / minimal air movement, the Z11 Pro II "stops" working at about 10 F. The stand-by current is very minimal (as my cheap batteries demonstrate), but it might be enough to keep things working if the tuner is sealed in a styrofoam box. Attic temps here range from -25F to +120F. (My older SGC tuner has never been temperature sensitive, but it's brain-damaged right now, so it needs attention. Plus, it seems to need a bit more RF to initiate a "tune," which has been frustrating at times when using 1-3 W radios.)

In case a box isn't sufficient, I'm open to suggestion about a teeny-weeny heat source that won't burn down my house like a rogue, unattended light bulb might, etc, as the tuner is in the attic and is only visible if I open the ceiling hatch from the top of a ladder :)

Something like a 2-watt Peltier module, etc?

As always, thanks for your input!

On Wed, Oct 30, 2013 at 11:54 PM, Kirk Kleinschmidt <kirk@... mailto:kirk@...> wrote:
MoonScryer,

I have successfully used loops of this type in the past with manual and autotuners.

Coupla thoughts:

1. The 30-W limit isn't really an issue, as FCC/common sense RF exposure guidelines would likely be exceeded at or beyond 30 W for an indoor antenna regardless of mode. Any more

than that and you're gonna couple RF into your ac wiring...with potentially bad results for delicate ac-powered devices... You'll also likely trip GFCI outlets and breakers...

2. I strongly suggest placing the tuner at the antenna feed point and placing the 1:1 coaxial balun on the input of the tuner. This will eliminate SWR losses in any coax that might run between the tuner and the antenna. With small antennas these losses can be extreme.

3. If you can't do that, use beefy 300-ohm twinlead (okay) or 450-ohm ladder line (better) or true open-wire line for the run between the tuner and the feed point (best). This will essentially eliminate any feed line SWR losses. Using coax between the tuner and the feed point with these physically small antennas can be cripping. 20+ dB losses are common.

I just proved that point in my own shack. I have a 40-meter horizontal loop that runs around the perimeter of my attic. My autocouplers (a Z11 Pro II and an SGC SG-231) live just inside the attic access hatch, which is mostly centrally located. This setup has been a star performer for years at 5-10 W, even producing DXCC (and soon 5BWAS) WAC on 80 meters and several DXCC entities on 160.

Because the SGC is slightly "goofy," and needing service, I switched to the Z11 two years ago. A 70-foot run of RG-6 connects my shack to the attic tuner, and a 25-foot (approx) run of open-wire line connects the Z11 to the feed point (no balun). Well, the balun (coax loops) is actually on the coax, right at the tuner input.

As mentioned, this works really well, and there are days I hardly notice that I'm using a compromise antenna. The Z11 doesn't like MN winter temps, however, so when it's 10 above (or colder), the tuner just won't tune. As a short-term remedy, I moved the tuner to a second-floor bedroom and ran 20-25 feet of coax from the tuner to the open-wire line (coaxial balun at the transition).

It TUNES sweet, but it's practically a dummy load compared to the previous setup. Before last weekend's CQWW SSB contest I put the tuner back in the attic, and POW! The good old days are here again! But winter is also coming...so I'll have to rig a styrofoam box with a low-wattage heat tape (or something) to keep the Z11 warm...or I'll have to fix the SG-231, which isn't affected by cold temps.

At any rate, I HIGHLY RECOMMEND placing the tuner at the feed point or using ladder line between the tuner and the feed point.

Good luck,

I'm using a half wave open loop in my attic. It's basically a 60 foot dipole bent into a rectangle. I have it fed at the corner with Radio Shack TV Twinlead into a MFJ 4:1/1:1 switchable balun, which is connected to the tuner(Z11 Pro).

I have the tuner in the shack because in my area with the extreme heat in the attic during the summer, I doubt anything electronic would last long up there.

Hi

I found this in the AT-11MP manual.

a.. Set R5 and R6 to the center position.
b.. Connect the transmitter and antenna (or dummy load) to the proper ports.
c.. With a voltmeter on test point REV (to the left of R5), and about 10 watts applied to a dummy load or resonant antenna, tune C1 for minimum DC voltage. The voltage should be just about 0.0 volts (0.1 is OK). You MUST use a 50 ohm load (either dummy or resonant antenna) to properly do the alignment.
d.. Raise the power to 100 watts and watch the forward needle on the power meter. Adjust R6 to read 100 watts on the forward meter. Be sure to start R6 from it's lowest value.
e.. Position R5 to the same physical position as R6.
f.. Note: if you can't get 100 watts out of your radio, use 50 watts and adjust R5 and R6 for the proper readings on the meter.
g.. Congratulations! The AT-11 MP is now ready to be put on the air.

Subject: [LDG-auto-tuners] How do I recalibrate my Z-100Plus

☐

Hi

I have been reading the "SWR Reading on Radio VS on LDG Tuner" Conversation.

I have a Z-100 for portable use (WWFF) and a Z-100Plus for home use.
The Z-100Plus always gives a worse SWR after tuning than the Z-100.
As I see it when I open the boxes they have the same LC configuration - so they should bee able to tune to the same SWR under the same conditions. (That is the same antenna, cables, grounding ect)

Dose any of you have a calibration describtion?

It would bee nice with a "how to calibrate"folder here in the Yahoo group.

A continuous impedance vs a change in impedance.

A: Source1 (SWR1) ==========(Z1)========== Load1
B: Source1 (SWR2) ----------(Z2)----------=========(Z3)===== Load1

Think about this for a moment. Source1 = 50 ohms. Load1 = 50 ohms.
Z1 and Z3 = 50 ohm coax, and Z2 = 75 ohm coax.

SWR1 NOT equal to SWR2

Taking this a bit further:
C. Source2 (9:1)==========(Z1)========== Load2
D. Source2 =======(Z2)==========(9:1)=====(Z1)========== Load2
E. Source2 ==========(Z2)==========(9:1) Load2

Source2 = 50 ohms. Load2 = 450 ohms. Z1 = 450 line. Z2 = 50 ohm coax.
And 9:1 = the balun.

It reallly doesn't matter where you put the balun in the above example. The
real difference comes with making Load2 NOT equal to Z1, and the resulting
SWR causing loss in coax. (450 ohm window line is comparatively low loss.)

For a given mismatch at the load, there will be more lose in E than there is
in C.

And now one step further:
F. Source3 ======(Z1)=====(9:1)==========(Z2)======== Load3
G. Source3 ======(Z1)=====(4:1)==========(Z2)======== Load3

Source3 = 50 ohms. Load3 = 450 ohms. Z1 = 50 ohms Z2 = 450 ohms.

In G you have an inherent mismatch of 2.25:1 Referring to example A and B
above, you have a discontinuity in the transmission line impedance. You have
a discontinuity in G just as well, if not more so.

Since you're older than me, you should remember using a 102' doublet antenna
with open wire line and a tuner. (Before they got rid of the tuner and terminated
the open line directly to a piece of 50 ohm coax and called it the G5RV antenna.)

The lengths of the doublet and feed line had a relationship that made for optimum
tuning. Nor did they suggest using randomly chosen pieces of different feed line.

In my case, I am running the classic '30s vintage 102' doublet antenna with 450
ohm window line and an LDG Z11 Pro II tuner. Using a 4:1 balun it was fussy and
would occasionally insist on retuning itself. Using a 9:1 balun it calmed down and
tuned reliably.

1. A random wire antenna fed with 450 ohm ladder-line just is not going to show 450 ohms resistive at the ladder-line to coax junction. So what? You're not going to get an opportunity to transform 450 ohms to 50 ohms using a 9:1 balun..

2. I borrow the following thought from a respected published ham and edit it for brevity. The use of the word "your" should be understood as a general "your" and in this case not pointing to any specific person.

" ... you can make many, many contacts with ANYTHING. So, enjoy your antenna and the contacts you're making. Without a reference antenna or an accurate model you have no way of knowing how good your antenna is in absolute terms. People make contacts every day on antennas that exhibit 1% efficiency... 1W radiated for every 100W pumped into the antenna. Antenna theory is based on real, physical fact. The occasional accidental antenna that works much better than expected is only due to incomplete information in the calculations or models. Your antenna works better than predicted only because you haven't measured how bad it is."

Mike, N2HTT, you can make your LDG tuner happy, and it will work well for you. Follow this link and read. I think it will help. Tom, W8JI, is an extremely well respected authority on these issues. I think if you follow the information here that will help make your Z-11ProII much happier.

How true. Back in the 1970's I was anxious to get back on the air after my military stint. I acquired an old Collins KWM2A and proceeded to tune it up to a dummy load. I was actually able to make a very local contact with another ham using just the dummy load. This gave me an idea. I put a tee connector between the rig and the dummy load and ran a piece of wire out the window and clipped it to the rain downspout. I made many contacts this way, but receive was definitely a compromise. The point is, it got me back on the air and making contacts.

If I had an LDG tuner back then I would have done a lot better!

Jeff:

Yup you have it right. I believe you're saying that SWR doesn't matter if you have low loss feeders.

If I sounded trite, its because this whole thread is easily answered by a peek at most any antenna manual, like my 1941 ARRL Antenna book (Volume 4) or the 2014 version - or most any version in between.

BTW., one can get a very good SWR at the transmitter end of any antenna of any length, on 160 through daylight, if there's 1000 feet of RG174 coaxial cable between the transmitter and the antenna.

There's a 1936 version of someone's antenna book (NOT the ARRL book) on the web someplace, which I downloaded. The specified lengths of feeders are chosen for ease of matching. However, in practice, almost any length of open wire feeder of 600 to 900 ohms (typical in those daze) could be loaded with the methods used in the 30's, and even in 1949 when my father got his license back after the war, and in 1951 when I was first licensed. We didn't worry too much about harmonic suppression, as long as one of those harmonics didn't bother military or commercial radio communications.

LDG makes it easy with their tuners - one doesn't even need to understand antenna and feedline theory unless one runs into some condition where the tuner won't match. Then the operator blames the tuner, and the manufacturer of the tuner, and doesn't even try to understand what is going on with the arrangement he or she cobbled together.

If a 9/1 balun works for you, FB OM, I'm not about to argue with results. But, please don't say that a 9/1 balun is a panacea for all cases where the LDG tuner doesn't find a good match.

I connected my 857d to the z100 plus including the Y-acc cable.
Their video show that by pushing the tune button, the rig is supposed to produce a carrier to start the tune process without having to hold down a straight key... that's not happening for me - I have to manually hold down the straight key to produce a carrier for the tuner to do it's thing. Is there a menu setting that I am missing?

Good evening to everyone.
I'm Rick, N8GGO and have been a ham since 1968.

About two years ago, I bought a new Yaesu FT-950 station with all the bells and whistles, but was never really happy, or content with the MFJ antenna tuner that I bought with the station.

Well, last week I finally corrected that situation by buying myself the LDG 100proII. With only time to play with the new tuner on Saturday evening, I wish I would have made this purchase a long time ago. I love the auto tune feature and the ability to "tweek" the settings when dealing with a difficult antenna.

I've had a couple of minor startup issues, but those were mostly due to some confussion of what I was reading in the manual (yes, I broke down and read the manual).

Anyway, I'm looking forward to reading the back posts on this group, and am open to hearing from any of you in the group that may have any tips and tricks for a new LDG user.

73,
Rick, N8GGO?

I am trying to buy an LDG RCA-14 Breakout Box for my recently acquired TS-2000x. If you have one you would part with please email.

As an aside, I wonder why this product was discontinuted? I was vaguely aware it existed but didn't realize the utility it represented until researching for the TS-2000. It seems to me it was very reasonably priced; why did it go away?

LDG seems to have done that a lot in the past.

The DWM-4 Wattmeter is a prime example.

Chuck,

This was discontinued once it reached a minimum amount of sales. We have a program here at LDG where we hire college students (not an internship for free) and they design small products (with supervision, of course) and get college credit toward their Electronics or Electrical Engineering degree.

Most of the time, there is little or no market for these products, but it helps the student with understanding the product development process. We've been doing this for over 10 years and many students have gone on to start their own companies.

It's our way of giving back while providing some small products to the market for a while.

Dick,

The DWM-4 was discontinued once LDG changed from direct sales to dealer sales (many years ago). Since the design required that each remote sensor be calibrated to the main display unit and there were three sensor options for each of the four ports, there was no way a dealer could carry this product "and" retain the high level of accuracy.

We contemplated a redesign to put the calibration parts in the sensor unit for a while. But by then, many other companies had copied (and some improved) the concept and it didn't make sense for us to continue on that path with such a diluted market.

Thank you for the answer Dwayne. Fortunately for me I was offered a New In the Box RCA-14 by a list member and it is now on its way to me. I might add that I was reminded of the existence of the RCA-14 while surfing eBay. I noticed there are several individuals there who seem to be making a business of making and selling adaptor cables for various radios. I remember what a pain in the rear it was to make a cable years ago for my then new IC-746PRO and did not want to repeat the process with eyes and skills that are eight years older now. You may have made the right business decision though because I also checked to see if MFJ made such an item and it appears they don't. Since MFJ seems to make any kind of accessory that is conceivable, it probably speaks volumes that they don't make this. I'm looking forward to using the RCA-14 on several of my radios.

---In LDG-auto-tuners@yahoogroups.com, <ldgyahoo@...> wrote:

Chuck,

This was discontinued once it reached a minimum amount of sales. We have a program here at LDG where we hire college students (not an internship for free) and they design small products (with supervision, of course) and get college credit toward their Electronics or Electrical Engineering degree.

Most of the time, there is little or no market for these products, but it helps the student with understanding the product development process. We've been doing this for over 10 years and many students have gone on to start their own companies.

It's our way of giving back while providing some small products to the market for a while.

6572. Untuned freq (no pun intended)

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2013-11-19 17:42:38 UTC
From: <rclayp@...>
Topic: 6572 Message: 6572

Hi LDG,

I have an AT-ProII. I don't like using fully automatic as the chatter gets in the way of the initial ragchew which is generally the most important part of establishing a QSO. What I have been doing is in semi-auto mode I usually go slightly "off freq" and mash the tuner button on my IC-7000. When the autotuner has finished I jump back to the QSO freq and establish a connection.

After that long winded discription my question is does LDG use the last stored tune value?

Does it interpolate between tuned freqs?

Does it strictly only use "autotuned values" from autotuned freqs and if you move off that you get whatever the wire is.

Finally if I raise/lower/adjust my G5RV does it matter that much? Do I need to reset LDG memory?

Thanks and regards,
Rob Claypool

I have an end fed 88 ft wire fed into a 9:1 unun fed into the tuner by 50 ft of premium rg-8x. When I check the swr with my antenna analyzer it shows 6:1. The at-200 will not consistently tune this. Nine times out of ten it flashes twice and does not tune. Any help would greatly be appreciated. Low end of antenna is about 20 ft high end about 35 ft.

Yes it stores that specific freq. in memory with the tune result... If your slightly off frequency the tuner if the Swr is lower than the threshold based on the closest tune will not initiate a retune. 1.7 is the default threshold. The tuner should maintain the fundamental bandwidth of the antenna. The frequency you initiate the tune will become the lowest Swr (should be) and now will become the center point of the range of your antenna...again your antennas bandwidth will determine how wide that range

And yes...if you raise or lower your g5rv the feed point impedance will change thus affecting your Swr thus changing the tuners match... If the match is still below 1.7 then it will not initiate a retune..

do you have a counterpoise on that end fed? Try grounding the tuner... it may work more consistantly... you may be getting RF into the processor... end feds are nasty with common mode.. grounding the tuner typically helps with those kinds of antennas.

If you haven't done so already, try a choke between the output of the 9:1 unun and the "50 ft of premium rg-8x". Make the choke from rolled up coax cable ('ugly balun' style) or place clip-on ferrite beads over the rg-8x where it connects to the 9:1 unun. Secure the ferrite beads with electric tape so they don't slide down the coax cable. You want to keep the ferrite beads as close to that unun as possible. My guess is you have unwanted RF from the unun onto the shield of the rg8x coax cable. If so, the preferred method is to stop that at the antenna end of a transmission line, not at the tuner/transceiver end.

Good luck with that end fed antenna project.

Don't make a ugly balun choke..it will add iductsnce and further throw off your impedance. Either use beads ... You will need about 7 of them of the 43 mix...or build or buy a guanella balun type which is more effective...end Feds that don't have a counter poise use the coax as the counterpoise...so don't choke it too close to the unun...I would suggest to choke it before it enters the structure...if you choke it too close you will impact performance....

You have 3 options with an end fed:

1. Counterpoise attached directly to ground rod - poor performance but will get rid of all common mode
2. Counterpoise equal length (elevated)
3. No Counterpoise - the shield of the coax will become the counterpoise...
4. If the antenna is close to the ground you can put MANY radials going in different directions... though 1 elevated will probably be more efficient...

Put the beads right before it enters the building or shack... You may need more beads depending on the option you choose above.

All:

Remember that some end-fed antennas, particularly the ones they claim don't require a counterpoise, present a high impedance at the feed point (i.e. 1/2 wave). The amount of reactance you need to provide sufficient isolation at that point is therefore much, much higher and a typical ugly balun, beads, and even commercial common-mode chokes may have limited or no effect.

If you want to provide isolation from your equipment you need the chokes at a lower impedance point along the transmission line some distance back from the feed point. If that's not near a 1/2 wave from the feed point, it will require much less reactance and a simple ugly balun or some ferrite chokes may do the job. But, of course, doing that can mess with the antenna feed-point impedance.

This is exactly why there is no such thing as an 1/2 wave end-fed antenna without a counterpoise. If you want to have a high impedance feed-point, you need another offsetting 1/2 (or multiple) wave element. If the feed point is well balanced, you might avoid some of this problem, but that may be hard to achieve.

Topic: 6585 Message: 6586

Remember, the 4/1 balun is an impedance transformer. The impedance at the input of the feeders can be almost anything, unless the antenna itself presents a load of 450 ohms resistive. I generally carry a 1/1 LDG balun because some times it provides a better match. Just because you have 400/450 ohm feedrs does NOT mean the output of the balun is looking at 400/450 ohms resistive.

And, it also helps to experiment with the length of the feeders, if you're planning to operate on multiple bands.

The best way to determine if one of the LDG baluns is working is to take the back off (there are four screws which hold it), and do the "smell test." If it smells or looks burned, the probability is very high that it has suffered from mismatch and overload.

Jim--
The simple way to check a 4:1 Balun is to connect a non-inductive 200 Ohm resistor across the high Impedance side and measure the impedance at the other side; it should be close to 50 Ohms.
However, your reason for using a 4:1 balun to connect to 450 Ohm ladder line are probably not valid. Just because the ladder line says “450 Ohm” on it has little bearing on the impedance at the end of the line. To know what the value really is, you need to do some measurements at the end of the line.
For checking the Balun and for other antenna measurements, you will need an antenna analyzer.

Topic: 6588 Message: 6588

I tried to send the folloing message to LDG using two addresses for them:

1. contact@ldgelectronics.com and

2. ldg@ldgelectronics.com

Both were undelivered. Any suggestions? zHere is the email. Any info on the topic or show of interest??

I read in the M-1000 meter manual table of contents that there was remoting info on page 8. I went to page 8 and fond the name of the document giving the remoting info for the AT-1000 Pro II. The document was said to be on the LDG web site. I can’t find it. Even if it has been “pulled” I would still like to read it if I may.

I am trying to learn as much as possible about the AT-1000 Pro II and any approaches that may lead to more fully featured remote operation as well as remoting the M-1000. I have come across a few hams interested in this and find a few mentions on the Yahoo LDG site. I have seen different approaches tried but I am not satisfied sufficiently to copy any of the work I have seen to date. Warranty considerations are not a major concern, just good engineering.

Any consideration would be greatly appreciated.

73,

Patrick AF5CK

Hi Bill,
I recently purchased and now use the LDG AT 100 pro ll with my Yaesu FT-950. These new tuners don't typically use interface cables, but are a easy to use as pressing the Mic key or start sending Morse and the tuner will handle the rest.
One note of caution is to make sure your rig has an auto power set-back if it senses a high SWR. The new Yaesu radios have this feature, including the FT-950. This feature will protect your finals during a full power tune, until the tuner gets your SWR down where it belongs.
Also, do not exceed the power rating of the tuner.
I hope this helps, and let us know how that new FT-3000 works for you.
73,
Rick, N8GGO.

Thanks, guys. I am pleased to say that I got a response back from LDG within an hour or so of posting. It pleases me that customer service/tech support is so good.

The answer, however, was a simple “no”. I asked him to expand a bit, and he did. The AT-1k wants to see a “contact closure”, not a “signal”. The Yaesu radios use serial encoding on the mini-Din. The rest of the world uses the contact closure. My conclusion is that we will not see any progress on this issue.

The next question I have for myself is that since the FT-950/3000 have built-in “TUNE” function; I.E., the Tune button causes a 10W carrier to be sent, is there a way to get a suitable “switch” signal to the LDG. Even so, the signal is so short the LDG does not have time to complete the tune. I think I will have to be happy for now going to AM set to 10W, hit MOX, then the LDG Tune. Because I run a KW, I cannot leave the LDG in Auto. Or, if I can lengthen the time on for the tune cycle, that will work.

I will be looking into all this over time, and will update with any good finds. 73, es TNX AGN,

Bill – K4IZE

(BTW, I currently have the FT-950 with the AT-1000 Pro II, but going to the FTdx3k)

I don’t know what logging program you use but I use Logger32 and have an FT9000 and an AT1000pro2.

I created a simple macro that: drops the power to 25 watts, puts the radio in RTTY mode and moves the TX frequency up 5 khz. When the macro is activated, have the AT1000 in semi mode ad press the tune button, usually a short press as most tuning solutions are in memory. After the tuning is done, I drop the tune macro (another macro) and the radio goes to CW at the original dial frequency at 100 watts.

On my FT9000, The Band Data 2 socket has a "linear" pin. My guess is
that this goes to ground on TX.

Might help.

While I haven't actually tried it with my 950 I believe you could use the linear jack to allow the LDG to command a carrier on. I believe the txreq line can be used aka the way a FT857 cable is made.

Great idea, Gerry. I use ACLog suite which I really love. I have not thought about macros. I will look into this when I get the FTdx3k installed – I think it has a simple macro program available on the Yaesu site. I am recovering from recent surgery and am not allowed to lift more than 10# so I guess it will be after the holidays before I get to swap out the radios. TNX es Happy Holidays,

Bill – K4IZE

6598. Rt-100 vs z11 pro ii

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2013-12-09 22:16:36 UTC
From: Jim Snider
Topic: 6598 Message: 6598

Anything software wise different between these 2 tuners??? I have the s9 43 ft with a z11 pro ii with a bias tee feeding power to the base of the antenna.

I don’t know what logging program you use but I use Logger32 and have an FT9000 and an AT1000pro2.

I created a simple macro that: drops the power to 25 watts, puts the radio in RTTY mode and moves the TX frequency up 5 khz. When the macro is activated, have the AT1000 in semi mode ad press the tune button, usually a short press as most tuning solutions are in memory. After the tuning is done, I drop the tune macro (another macro) and the radio goes to CW at the original dial frequency at 100 watts.

Subject: RE: [LDG-auto-tuners] Re: Impression of LDG AT 1000 PRO II vs LDG AT 100 PRO II

Thanks, guys. I am pleased to say that I got a response back from LDG within an hour or so of posting. It pleases me that customer service/tech support is so good.

The answer, however, was a simple “no”. I asked him to expand a bit, and he did. The AT-1k wants to see a “contact closure”, not a “signal”. The Yaesu radios use serial encoding on the mini-Din. The rest of the world uses the contact closure. My conclusion is that we will not see any progress on this issue.

The next question I have for myself is that since the FT-950/3000 have built-in “TUNE” function; I.E., the Tune button causes a 10W carrier to be sent, is there a way to get a suitable “switch” signal to the LDG. Even so, the signal is so short the LDG does not have time to complete the tune. I think I will have to be happy for now going to AM set to 10W, hit MOX, then the LDG Tune. Because I run a KW, I cannot leave the LDG in Auto. Or, if I can lengthen the time on for the tune cycle, that will work.

I will be looking into all this over time, and will update with any good finds. 73, es TNX AGN,

Bill – K4IZE

(BTW, I currently have the FT-950 with the AT-1000 Pro II, but going to the FTdx3k)

Subject: [LDG-auto-tuners] Re: Impression of LDG AT 1000 PRO II vs LDG AT 100 PRO II

Hi Bill,
I recently purchased and now use the LDG AT 100 pro ll with my Yaesu FT-950. These new tuners don't typically use interface cables, but are a easy to use as pressing the Mic key or start sending Morse and the tuner will handle the rest.
One note of caution is to make sure your rig has an auto power set-back if it senses a high SWR. The new Yaesu radios have this feature, including the FT-950. This feature will protect your finals during a full power tune, until the tuner gets your SWR down where it belongs.
Also, do not exceed the power rating of the tuner.
I hope this helps, and let us know how that new FT-3000 works for you.
73,

Rick, N8GGO.

6600. AT-11MP dead?

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2013-12-14 17:35:11 UTC
From: <ygroups@...>
Topic: 6600 Message: 6600

I had an electrical storm hit a month ago. Lost NUMEROUS devices in the house and think the auto-tuner may have been overlooked on my first pass.

When I try to use it the forward power goes to 10watts when I know the radio and antenna are matched pretty well. I remove the auto-tuner and the radio output does not fold back. I suspect the tuner took a hit. Any quick troubleshooting tips from anyone?

You should simplify the situation for testing. I hope you have a 50 ohm dummy load you know is good. It would be good also to have a couple of 2:1 or 3:1 dummy loads (100 ohms and 25 ohms, 150 ohms and 17 ohms). If you can throttle your rig down to just a couple of watts you can make these with resistors from Radio Shack, obviously if you don't have a low power option additional dummy loads will not be so easy to make.

6603. AT-200 Pro Noise Question

Yahoo group: LDG-auto-tuners (2010 — 2017)
Date: 2013-12-21 14:19:44 UTC
From: Mike Carletta Sr
Topic: 6603 Message: 6603

I am a new member to Group.
Have a question that has been on my mind for a while.

When I insert my Tuner in line I see a 30 db jump in noise. Take it out and it disappears.

I originally had antennas that needed help in tuning but since I have improved them. That is how I can tell the difference.

The question is my AT 200Pro (2 years old , has been back to factory once already) not working properly?

I use a Flex 3000 into a beam and a dipole.Tuner in Flex does the tuning now.

Mike:

Try this. Put your tuner into bypass mode and note the noise level. Now disconnect the power connector to the tuner and note the noise level. Finally, disconnect the radio control line and note the noise level. (Do this with the antenna cables connected to the tuner.)

Does the noise level decrease as you disconnect the power and control lines? If so, then it's a design problem that's common with many of the LDG tuners. I can explain further if this is what you're seeing.

Every LDG tuner that I know of, battery powered or external D.C. powered, the CPU is either turned off or goes to sleep when not transmitting, so it may be possible that the tuner is defective?

Craig:

I don't believe his noise is coming from the tuner CPU. Most likely coming from something nearby. Many LDG tuners are actually quite susceptible to noise coming in on the power and control lines. I think that's what he's getting.

Mike,

From your description, there seems to be just two probabilities - the tuner could have gone bad; or, the coax jumpers have an open or short. Putting the tuner inline required an additional jumper. Try changing that out first. I don't have the LDG 200, but it should have a bypass setting. If you lose the noise in bypass, but have it in tune, then the tuner becomes the culprit. Good luck with it. 73,

Bill - K4IZE

If you have a mismatched antenna, the background noise will become less when the tuner is in bypass since you no longer have the benefit of the tuner providing a proper match.

Art:

That may be expected. What kind of antenna are you using it with on 75-40? If the antenna isn't resonant, then there will be more receive signal to your receiver after the tuner has provided a match solution. More signal means more noise, and the lower bands generally have more noise anyway. The received signals should also increase in proportion to the noise in this case. In bypass mode there's no match to the antenna, so less power transfer of received signals to your receiver.

Santa's Helpers,

First off thank you all for your comments.

My layout to be exact is: 4 antenna's> 4 way switch> AT-200 Pro 11> Flex 3000. system is well grounded.
Here are the results of todays testing:

Freq 80 Meters SWR 1.2;1 Noise level -110 db OFC dipole up 30 ft rig tuner in by-pass, no snow or ice present
Removed:
1) tuner in by-pass -120 db via tune button red LED on for By-Pass
2) no power -140 db power plug removed
3) no ant -140 db removed lead from ant switch

Mu question is the same. Why the difference (-140 db - -110db= 30 db) difference?

Difference varies with band and time of day. This variant is the problem. Going back I often can not repeat my findings.

Seems to me like Tuner has amplifier stage..or possible component is going out of tolerance?

OK, this is dumb… but I've been known to say/do dumb things before. I have had my LDG-1000 switch to Ant-2 when I would swear I didn't touch it. Craig's description is what I saw. I suggest you find some kind of signal on one of the suspect bands and carefully note the strength/noise in Bypass; then Tuned, then in Ant-1 and Ant-2. Maybe straight into the XCVR as well. Since you do not need to xmit, try placing a 50-Ohm resistor across the Ant-in to the tuner. Make a simple chart of the results as you go. Put it in a msg and let all us would-be experts look it over. My apologies if the LDG-200 is totally different. Just ignore me.

One final thought then I will shut up. Try powering the TUNER ONLY off a battery. Switching pwr supplies are famous for their noise.

I'll be quiet now… Good luck with this. 73,

Bill – K4IZE

Great observation! Now, if he takes the antenna coax off and the noise
is still present, it is the tuner.

The antenna that I'm using for all bands 75-10 meters is a "Home Brewed"
wire dipole horizontal configuration,that is about 20 feet off the ground , and is laying
on my 3 tab single roof { due to antenna antenna restrictions } .
  I have used MFJ tuners in the past,and didn't notice the noise until after putting
and LDG AT 200 in line,and this past year replaced that LDG 200
with an LDG AT1000PRO11 .
  The dipole is resonant on 75-40 { 2 sets of wire }, and 20 meters .
  The LDG AT1000PRO11 lets me use the wires from 75/80 to 10 meters ,
 since putting the 1000Pro11 in line ,with good signal reports . I have worked
around the world on digital modes with no more than 30 watts outs, { if that makes a
difference,just thought I'd throw that in }.
  Don't get me wrong,I really like the LDG products,I was just wondering about the noise
on 75 and 40 meters .
  73, Merry Christmas everyone,
Art

You're missing at least one data point. Take the tuner completely out of the circuit. Use a barrel connector or similar to connect where the tuner is located.

Measure the noise, compare it to the noise with the tuner connected.

That will tell you if it's something happening inside the tuner, or if it's a quirk in your setup.

Another troubleshooting trick would be to find a local ham who operates on the same bands as you, arrange to visit his shack, install your tuner, and see if the results are similar. That could tell if something in your particular setup is amiss, and/or pinpoint the problem to something within the tuner. Diagnosing such a problem from afar, using this forum, is often helpful, but local help is generally orders of magnitude more useful.

To answer your first question. All electronic circuits are subject to defects. You didn't say if the LDG tuner was new out of the box, still in warantee or whether you picked it up at a hamfest, or someone gave it to you with a known defect. In all the above possibities, the answer is "Yes, it could be a defective tuner."

Mike:

Your numbers could mean a couple of things. One is that on 80 Meters you may just have a -110 dBm noise level with that antenna when it's tuned since it dropped to -120 when you went to bypass mode.

The other thing is that you went down another 20 dB when you pulled the power cord from the tuner. If the tuner is working correctly, this shouldn't happen. This difference may very well be due to common-mode noise entering the tuner via the power connector. The reason this can happen is that LDG has decided to isolate the control section ground from the RF section ground in many of their tuners. The picture below (if it makes it through the mail list) shows a jumper between the section grounds with a ferrite choke over it. (The picture is not from an AT-200 but will give you the idea.)

The problem with this is that it allows RF noise to enter on the power and control connectors and that RF can then be radiated inside the case by the entire control section of the board. Since the control and RF sections are intermingled on the board, there's plenty of opportunity for coupling of this noise to RF paths inside the tuner. As a result, if you have noisy devices in the area of your equipment, like a computer, some of that noise will likely end up injected into your signal path inside the tuner.

In our case, we had several LDG tuners operating in noisy environments with lots of computers and other equipment nearby, but in one particular case the antenna was several hundred feet away. Simply pulling the power connector (while in bypass) dropped the noise way down at that location. I replaced the choked jumper with just a straight wire and that pretty much eliminated all that extra noise. Doing the same made a couple S-Unit difference at the other locations.

I frankly don't understand why they built them this way, but it's pretty clear doing so is allowing noise around the shack to get into the tuner and into the user's receiver. In many cases I suspect the noise caused by this is below the noise level people see from their antennas, but those who are running computers or other noisy devices around their radios may see more of a problem.

So, that's where I think you are. If you check the higher bands, you might find that pulling the power connector will have a greater improvement. For 80 meters at your location, it may not really make much difference due to the higher noise coming in from your antenna, which varies with conditions (as you seem to report).

So I have an IT-100 that i've been using for a couple months with my IC-7600 to tun a G5RVMax antenna across all bands. Worked great till now.

Today i start getting 4 red leds "No RF detected" and no tuning operation. I tried replacing the feedline between radio and the tuner - no change.

I'm thinking that something in the tuner went bad as the radio will tune the antenna itself with its internal tuner (on a subset of the bands) and everything works with the tuner not in the loop.

IS this just a send it back situation? (I asked this question on reddit and someone suggested the tuner's memories being "full" might cause this and i should reset it, but i dont know how to do that.)

It's been a while since I've been under the hood of an AT-200 but does it use latching relays like the lower power tuners, or momentary relays like the AT-1000? If you can hear the relays click when you remove the DC power plug then they are momentary and might explain what you are seeing.

73 and Merry Christmas,

Craig

So i figured this out and its fixed.

Turns out, i was using Ham Radio Deluxe to do some Digital modes and it has a slider marked "Drive" which had gotten turned down (when i meant to turn down RF Power).

That sets something in the radio that causes it not to generate very much power when the TUNE button is pressed. (or at all acutally).

Turns out, resetting that and reconnecting the tuner and doing a forced manual tune and voila its working like a champ again.

The "not enough RF power" really *was* Not Enough RF Power. I just couldnt figure out why the radio was not generating the power till i had HRD up again and saw that i really wasnt getting power even on FM or RTTY mode.

I still dont know what DRIVE does, but apparently it lowers the output power by a lot.

<<< I still don't know what DRIVE does, but apparently it lowers the output power by a lot.>>>

The "Drive" control adjusts the level of the signal being sent to the XMITTER. I have a SignaLink that has a physical knob to do this. I set the knob to 12 O'clock, then adjust the mic gain on the XCVR to barely show the first block of ALC while xmitting a data string. You then adjust the interface "Drive" (or whatever) until your power is what you want. The software I often use has a Tune button that sends out a solid tone just for this purpose. I do not use HRD so I cannot be sure in your case. I may take a look at the latest HRD and see how I like it. A "Drive" adjustment that works in SSB and CW would be nice as my radio requires going to a menu to set power. 73

Good job, Bill – K4IZE

Subject: [LDG-auto-tuners] RE: IT-100 4 red lights

So i figured this out and its fixed.

Turns out, i was using Ham Radio Deluxe to do some Digital modes and it has a slider marked "Drive" which had gotten turned down (when i meant to turn down RF Power).

That sets something in the radio that causes it not to generate very much power when the TUNE button is pressed. (or at all acutally).

Turns out, resetting that and reconnecting the tuner and doing a forced manual tune and voila its working like a champ again.

The "not enough RF power" really *was* Not Enough RF Power. I just couldnt figure out why the radio was not generating the power till i had HRD up again and saw that i really wasnt getting power even on FM or RTTY mode.

I still dont know what DRIVE does, but apparently it lowers the output power by a lot.

I hope, even though the Z100 is an old model, that someone can give me some ideas about what happened to me today.
I was on 15M with my FT-897 running 100W, and had tuned up using the Z100 quite satisfactorily. In the middle of a CW QSO, my radio went belly-up, did a complete reset, blanking out all my memories and resetting my menus to default values, but it stayed powered up!
Luckily I had used CHIRP a few months ago to make an image file of the radio's mems and menus, so I could upload that and get back to normal. But I'm mystified by what happened: suddenly the swr indicator on the radio went full scale, and blammo!
Googling brought a suggestion that perhaps some RF got from the tuner into the radio, since the tuner sits right on top of the rig. I don't really have any idea what happened, and as soon as I recovered from the shock, I got back on frequency, retuned and carried on as I had been previously. No subsequent problems.
Any ideas or thoughts or flashes of insight very welcome.

Thanks in advance,
Peter KO6R

first off.
It's never a good idea to have items stacked one on top of the other like you discribed.
